This book gives many items of good advice and some useful information as to a child's makeup and how to meet the needs based upon this. It is written, however, from the old standpoint of a superficial laying out of facts to be thus examined and talked about. Such advice fails discouragingly, and why? The message to be brought over to parents and to doctors today, and brought forward forcibly, practically, is that of a dynamic nature within the child, affectively charged; determining his likes and dislikes, his manifestations of detrimental habits, his willfulness, negative and inhibitory as well as actively directed; the fundamental condition of his "nervousness" as of that of his parents. The book scatters itself in its disconnected homilies on proper care and attention. It evades these issues of cause and effect which necessitate a deeper understanding of the child's nature. So much good fact in the book, if only brought together and vitalized by the inner truths of the child's psyche!

FICTIONAL ANTHROPOLOGY

The Long Journey. Fire and Ice; The Cimbrians; Christopher Columbus. By Johannes V. Jensen. New York: Alfred A. Knopf, 1923, 1924.

Man is a migratory animal. This is the song of his travels. This, and nothing more. That Jensen has produced an epic in part and in part a treatise, is not his fault. Neither is the fault in his material. Man wearies of sustained effort. He must be ever seeking something new, aching to be on with it, leaving usually the last bit of his present task a trifle rough lest he lose the golden dream of the new. And this is what seems to have happened in Jensen's trilogy. Moreover, his imagination flames to primitive man, to man in the struggle years. When most of the conflict with Nature is eased, and only the dramatic conflict of souls is left, his theme does not grip him in quite the same way. It is a difficult picture to maintain, one man embodying the seething mass of scarcely human beings fighting their way through *Fire and Ice* to the barbaric Cimbrian days—to reach, finally, Christopher Columbus, one man who blots out the seething mass, not of human beings any more, but their puppetlike unchanging ideas. This shift, accidental or otherwise, weakens the powerful hold of the story. It must have weakened the author's interest, or else betrays his flagging effort.

No other writer has so vivified life for us. We know in theory about Neanderthal man, homo Heidelbergensis and all the later comers. But Jensen has *felt* them, dreamed their lives, lived them through long years of minute ethnological research. They still live to him—a prototype of his hero *Guest,* passing the aeons in review by all the aids of science.

Fire and Ice, the first volume in the English translation, is the story of man's rise from beast. The possession of fire aids him in his climb. Adaptation to environment follows. Man can begin to live where he chooses. Man like his predecessors, plant life, animal life, increases to the point of self destruction. Man being movable, does move.

Then in *The Cimbrians* we have the migrations. Then comes the conflict of man and man—the building up of memory, history, mentality. The grindstone of mental contacts, civilization. Rome totters before the wave of barbarism, just as in Yucatan, human carved wonders have succumbed to the wave of vegetation springing into its own again. And if Rome conquers it is only a respite. Minds become more subtle, destruction more intense, conditions more vile. The old world must expand or suffocate in its own combustion.

And so, *Christopher Columbus.* This is the epic, not of the rise of man, but of his downfall. The author may not have intended it as such, but he has clanged a truth. Man is destroying himself by the misapplication of "progress." So long as progress meant creative effort there was beauty. So soon as "progress" became conscious, there was room in man's soul only for greed. A long journey, and maybe futile. Let us at least admit the possibility and cast about for the cure.

MILITARY MEDICINE AND PHARMACY

Report of Second International Congress of Military Medicine and Pharmacy. Rome, May-June, 1923. By Commander William Seaman Bainbridge, M.D. Reprinted from *The Military Surgeon,* December, 1924, January and February, 1925. Washington: The Military Surgeon, 1925. Pp. 148.

This report covers such subjects as evacuation of the wounded, collaboration of military and civilian authorities in matters of national health, disinfection and disinfestation, treatment of chest wounds, and chemical laboratories.

The international viewpoint is well maintained through the collaboration of representatives from twenty-seven countries.

Medicoliterary Notes.

The *Yale Review* for April contains several popular yet authoritative articles on scientific and sociological subjects, among them The New Physics and the Stars, by Henry N. Russell; The Child and the Law, by Agnes Repplier; Democracy and Education, by James Rowland Angell; Southern Spindles, a comment on the future of industry in the South, by Broadus Mitchell; and Insular America, by William Howard Gardiner.

* * *

The European press has recently been commenting on the establishment in April of a new organization, the British Institute of Philosophical Studies. The aim of the new institute will be to apply the principles of philosophy to the present unsettled conditions of political, industrial and social life, and to encourage the study of philosophy by the general public. The Institute will offer both day and evening courses, and will also give advice and other assistance to those wishing to read along philosophical lines. A research library will be established, and public conferences will be held for addresses and discussions on philosophical subjects.

* * *

Aesculape (Paris) for February contains an article by R. Tait Mackenzie, professor of physical education at the University of Pennsylvania, on Facial Expression Under Stress. Several excellent plates are included of masques

from faces showing various forms of expression, such as effort, fatigue, and exhaustion. Another article with interesting illustrations is on the Manor of Laennec, by Dr. De Backer and Dr. Larbaud.

* * *

The Equipment of the Rolls-Royce air express of Imperial Airways, in which the first aerial cinema show will be given whilst the machine is in flight, has been completed. The cinema projector has been installed in the luggage compartment at the rear of the passenger cabin, and the screen erected against the bulkhead which separates the passengers from the pilot's cockpit. Fourteen spectators will be accommodated in two rows of armchair seats running down either side of the cabin. The star picture is advertised by big streamers on either side of the air express.—*Manchester Guardian Weekly.*

* * *

Books announced for the month are *Concerning Evolution,* by Prof. J. Arthur Thomson, of the University of Aberdeen (Yale University Press); *African-Armenian Mythology,* by Alice Werner and Mardiros Ananikian (Mythology of All Races Series, Marshall Jones Company); *Concerning the Nature of Things,* by Sir William Bragg (Harper); *The Spirit of the Hive,* by Dallas Lore Sharp (Harper); *Everyman's Genius,* by Mary Austin (Bobbs Merrill Company); and a new unabridged edition of Boccaccio's Decameron, with illustrations from etchings by Clara Tice (Boni & Liveright).

* * *

Considerable interest is being manifested in England, judging from press reports, in the opening of the box of prophecies made by Joanna Southcott in the early eighteen hundreds. One of these boxes has been already opened by a man in Hammersmith, to whom it was left many years ago by a woman who swore that infinite curses would be showered upon the head of the opener. The gentleman, however, became tired of having the box in his cellar and opened it, and a whole mystery story could be woven about the incident. The box was small, charred by fire, and bound with iron bands, roped and sealed and screwed together. Inside was found an old copy of the New Testament, between the covers of which were a wisp of gray hair and a torn scrap of parchment on which was written the following prophecy: "At that time there shall not be wanting signs of these things to come. Bones of unknown creatures, as many as there are bishops, shall be dug out of the earth, and monsters of the Lost World shall live, and men shall be made to wonder . . ." Which suggests the statement that the moving picture, The Lost World, by Sir Arthur Conan Doyle, is excellently filmed and well worth seeing.

George W. Alger has contributed an article of unusual interest to the *Atlantic Monthly* for April entitled Leisure—For What? The writer believes that the large amount of crime in this country, wholly out of proportion to crime in other civilized countries, the prevalence of the use of habit forming drugs, and our large insanity records, are partly caused by the vastly increased amount of leisure, together with the decrease of pleasure and interest in work, which marks present day industrial conditions.

Shaw's *Cæsar and Cleopatra,* which opened the Theatre Guild's new playhouse in New York City, is running also in London at the Kingsway Theatre.

* * *

An English producer has made a motion picture play of Alfred Ollivant's famous dog story, *Bob, Son of Battle,* and it is reported to have had a brilliant opening at the Tivoli in London. The stars of the production are two of the greatest sheep dogs of the Cumberland Downs, and the supporting cast of humans is headed by James Carden, Ellen Terry's husband. An American producer has secured the rights for this country and the film will be shown here soon. In this connection we are reminded by Mr. Ollivant's American publishers, Doubleday, Page & Company, that *Bob, Son of Battle* had its greatest success here. About 175,000 copies of the book have been sold in this country since it was first published in 1901.—*New York Times.*

* * *

India, it seems, is fast becoming the favorite source of supply of the monkeys that furnish the glands for the new thyroid treatment. This seems a curious coincidence when we remember that in India the tradition and sentiment of all classes is to protect monkeys from destruction, and that in certain localities and in all the places of pilgrimage monkeys are fed regularly and to kill one is a great crime.

* * *

Flying hospitals have been added to the equipment of the British army in Iraq. Each carries a doctor, a nurse, and several beds for patients, and is driven by a specially silenced Napier engine of one thousand horse power. These flying hospitals will travel a hundred miles an hour from their bases to the scene of skirmishes, and, after treating milder cases, will take the more serious casualties on board and fly with them to the nearest base hospital, with the necessary treatment being supplied enroute.

The first real international conference on education will be held in Edinburgh from July 20th to 27th of the coming summer. The plan originated in this country two years ago during the National Education Association conference in San Francisco, to which invitations had been issued to various nations to send delegates. These invitations were accepted by the educational organizations of Great Britain, Canada, India, China, Japan, Italy, Czecho-Slovakia, and Greece; and at the San Francisco meeting it was decided to organize a World Federation of Education Associations, which should summon a world conference to meet in 1925.

Girls employed on a monotonous process in a bleaching factory were given two rest periods of forty-five minutes each during the day. On the advice of an expert, the régime was changed to twenty minutes rest after every eighty minutes of work, with the result that output was increased sixty per cent.—*Industrial Psychology and the Production of Wealth,* by H. D. Harrison.

* * *

In Switzerland in the eighteenth century prostitutes and courtesans were sentenced to the labor of street cleaners and refuse collectors. They worked in squads, supervised by a policeman with a cane. Part of the squad hauled the large wagons about the others cleaned the streets and shovelled the refuse into the cars.—*Aesculape.*

* * *

Pirandello, the Italian playwright, has established in Rome a repertory theatre which will be run for art, not commercial interests. The plays of all countries will be produced, including some of those of George Bernard Shaw, G. K. Chesterton, and Lord Dunsany..

* * *

The *Forum* for April seems largely given up to debates. The discussion pro and con Roman Catholicism, which began in the March number, is continued through an article by John Jay Chapman, who replies to a challenge from Michael Williams, Catholic editor and author, in the March issue, to the opponents of Catholicism to submit a specific bill of complaints against his church. To Mr. Chapman's reply to this challenge, Dr. Frederick Kinsman, formerly Protestant Episcopal Bishop of Delaware, now a Roman Catholic layman, will write an answer for the May issue.

* * *

Another debate in the April *Forum* is on the subject, Is Crime Preventable? between Neil McCullough Clark, whose argument is entitled What's Bred in the Bone, and Walter B. Pitkin, who writes on The Intelligent Criminal. Other articles of interest are What Is Civilization? The Age of Pericles, by Paul Shorey; The Credo of a Naturalist, by Henry Fairfield Osborn; Our Democracy of Bad Manners, by Elizabeth Robins Pennell, and Has America a National Style?, by Johan Bull.

* * *

Among recent Macmillan publications of interest is *Pascal D'Angelo, Son of Italy,* poems written by an Italian immigrant who struggled through starving and bitter suffering and work on the roads to write and sell his book.

Abstracts from Current Literature

ARTHRITIS

Observations on Arthritis.—L. T. Swain (*Journal of Bone and Joint Surgery,* July, 1924) states that arthritis is more than an infection, it is a problem of physiology and chemistry, a problem of foods, assimilation, and excretion. In atrophic arthritis the skin secretions are found to be abnormally acid. Recovery from arthritis is dependent on several factors: the removal of infection where possible, the type of food, assimilation and excretion, the general resistance secured by normal physiology and chemistry. This is aided by the normal physiological use of the body through corrective exercise and better body mechanics.

Age Factor in Hypertrophic Arthritis.—T. A. Willis (*Journal of Bone and Joint Surgery,* April, 1924) says that hypertrophic bone changes represent the reaction of bone and joint structures to the wear and tear of life. They are more pronounced in certain types of individuals and are aggravated by continued local irritation of any character. These changes rarely occur before the thirty-fifth year of age, but are progressive thereafter. They may exist to a marked degree without clinical symptoms, being the result of metabolic changes rather than the cause, their presence does not prohibit relief from such symptoms. The bone changes are permanent. Treatment of the symptoms must be directed toward the removal of all possible sources of continued irritation. These include mechanical strains, focal infections, intoxications, and absorptions.

Attempts to Transmit Rheumatic Fever to Rabbits and Guineapigs.—C. Philip Miller, Jr. (*Journal of Experimental Medicine,* October, 1924) attempted to transmit rheumatic fever to rabbits and guineapigs by injecting them with various materials obtained from patients suffering with this disease. The materials used were whole blood, serum, joint fluid, pleural fluid, throat washings, and tonsil tissue, thus including the materials which might rationally be assumed to contain the virus of the disease during its acute stage. Throat washings and tonsil tissue were chosen because of the frequent association of tonsillitis with rheumatic fever. Twenty-seven rabbits and fourteen guineapigs were used. Transfer inoculations, i. e., from rabbit to rabbit, or guineapig to guineapig, brought the total number of animals used in these experiments to sixty-seven rabbits and forty guineapigs. Only two developed an acute nonbacterial arthritis. No other evidence of successful transmission of the disease was obtained. About half the rabbits and two thirds of the guineapigs showed myocardial lesions consisting of interstitial accumulations of lymphocytes and endothelial cells. Similar lesions were found in control animals.

Rheumatoid Arthritis.—Norman Kletz (*Clinical Journal,* November 5, 1924) says that in acute cases the first essential is rest. The joints should be placed in the position which ensures greatest comfort, being supported, if necessary, by suitable splints. The pain and local inflammation can best be relieved by hot applications such as hot flannel fomentations, if necessary applied over glycerinum belladonnæ. Quinine salicylate in doses of two to five grains three to four times a day is often useful, though in many persons toxic symptoms are rapidly produced. Great relief can usually be obtained by the occasional administration of a powder consisting of four grains of pyramidon, five grains of phenacetine and five grains of aspirin. The activity of the excretory paths must be efficiently maintained, and sleep secured, if necessary by the use of opium preparations, such as Dover's powder, nepenthe, or even morphine hypodermically. This treatment is, of course, largely symptomatic and palliative. The best way to attack the toxemia is by intravenous protein injection. Various proteins have been used, the safest and most effective probably being dead Bacillus coli. The initial dose in the acute stage should be from twelve to fifteen millions. This is diluted to ten c.c. with bacteriologically sterile and chemically accurate normal saline, which should be freshly prepared, and at normal body temperature. An all glass syringe should be used and the material injected slowly into a vein. The author has never known any serious disturbance to occur, and the effect on the joint condition and general constitutional symptoms is often striking. Not infrequently a few injections at weekly intervals appear to limit the condition completely.

A suitable initial dose in subacute or chronic cases is from twenty to twenty-five millions. The injection is usually followed in a few hours by symptoms of discomfort, headache, nausea and even vomiting, with shivering and pyrexia usually about 100° to 101°. These symptoms rarely last for more than twelve hours. Severer reactions are unusual. The injection should be given over a period of several months, at weekly intervals. So long as the dose produces an adequate reaction it does not require to be increased. The results are gratifying. Even in chronic cases, where deformity is extreme and fixation marked, some improvement can be obtained in the direction of increased mobility and relief of pain.

After the acute symptoms have subsided, and in the more chronic cases, confinement to bed is not only useless, but harmful. The patient should be encouraged to move about, and the affected joints kept mobile by means of radiant heat, massage and passive movement. This is absolutely essential in order to maintain functional activity of the joints and prevent the adhesions, and contractures, which are such striking and distressing features of neglected cases. Drug treatment is valuable even apart from the relief of pain. The old fashioned combination of potassium iodide and guaiacol carbonate is of limited value. Improvement sometimes results from collosol iodine and collosol sulphur given in doses of one or two drams in water, thrice daily after food, for alternate weeks. These preparations must be persevered with for long periods. Iodolysin and fibrolysin have been recommended and sometimes appear to be effective.

Surgical Treatment of Osteoarthritis.—C. M. Page (*British Journal of Surgery,* July, 1924) states that the two primary indications for recourse to radical operation are persistent pain, and progressive deformity in relation to the joint affected. There are four procedures, viz., excision of the joint, arthroplasty, erasion of the joint, and synovectomy. The aim of these operations in regard to the final function of the articulation varies considerably. The decision as to which one to employ, as well as the nature of the aftertreatment also vary in respect of different joints.

In the hip joint the choice of operation depends little on the anatomical condition or etiology, but is determined by the age and general condition of the patient. In the young and middleaged the aim is not only to remove pain but also to provide a stable joint, which is effectively obtained by complete erasion of the joint producing an arthrodesis, followed by fixation in plaster of Paris. In elderly feeble patients an arthrodesis should not be attempted, as it is often followed by pain in the lumbar spine and sacroiliac joints. Simple excision of the head of the femur is favored.

The problem of avoiding the secondary development of adduction deformity after operation only arises when a fibrous joint is the result. If firm bony ankylosis is obtained in a good position by means of proper fixation the difficulty does not arise; but it should be remembered that sound bony union is not always obtained, however carefully the operation may be carried out, and that union apparently firm, if due to fibrous tissue, is liable to gradual stretching. In all cases, therefore, of operations of this nature, the two simple mechanical factors above enunciated should receive attention, viz., preservation of the full function of the gluteus medius and minimus and tensor fasciæ femoris, and the preservation of the neck of the femur at as full length as possible.

For the knee a radical cure of osteoarthritis can only be obtained with certainty by arthrodesing the joint. Such a final destructive procedure is only justified in those cases in which pain is severe and persistent, or in which absorption of the bone of the outer condyles has deformed the joint. Synovectomy, when practised on those cases in which the chief and apparently primary change is in the synovial membrane, has given satisfactory results.

The operative technic for hip joint is described through three separate routes, the posterior, the superolateral, and the superoanterior. Of these the first route is discarded as unsatisfactory, the second is the most satisfactory for old

patients on account of its rapidity and the small amount of muscle section required and the third, giving the fullest exposure of the joint, while proving easily workable for children, is not for adults as satisfactory as the supero-external route.

In operating upon the knee establishment of union by fibrous tissue may be counteracted by attention to the following details: The synovial pouch should be dissected out, the bulk of the synovial tissue in the joint being in this way removed. The section of bone should be so planned that vascular cancellous bone is exposed everywhere except at the margins. Close apposition of the cut bone surfaces is usually assured without any special splinting, by pulling the patella down to the level of the tibia and pegging it in position there. The articular cartilage of the patella is previously cut off. The bone is most effectively held by means of a long French nail. This procedure holds the bone surfaces firmly in contact by the tonic pull of the quadriceps muscle and its opponents.

The author concludes his studies with a tabulated report on thirty-four cases of osteoarthritis treated by operation.

Effect of Pressure on Articular Surfaces.—D. B. Phemister (*Annals of Surgery,* October, 1924) offers the following conclusions: In pyogenic arthritis articular cartilage is killed and broken down first at the points of contact and pressure of opposing articular surfaces. In tuberculous arthritis articular cartilage is not killed first, but is protected at the points of contact and pressure of opposing articular surfaces. Cartilage is extensively destroyed first along the free surfaces, where the tuberculous granulations can grow onto and remove it. It usually disappears last in the regions of contact and greatest pressure in the joint, where it is detached and killed by undermining granulations and is then partly eroded by pressure of opposing bony surfaces. Proteolytic ferments derived largely from polymorphonuclear leucocytes assist greatly in the rapid removal of necrotic cartilage in pyogenic arthritis. Proteolytic ferments are absent in tuberculous arthritis, and masses of dead cartilage may persist for months or years, showing few signs of progressive destruction. In pyogenic arthritis the infection rarely invades secondarily the deeper portions of the bone at the points of pressure. In tuberculous arthritis invasion of the bone at the points of pressure is of common occurrence after the articular cartilage has been largely or wholly destroyed. The invasion is frequently on both sides, in which case it may lead to the formation of kissing sequestra at the points of greatest pressure in the joint. Weight extension should be applied during the active period of pyogenic arthritis to lessen the amount of invasion and destruction of articular surfaces at the points of contact and pressure. On the other hand, it would appear that extension for preventing the destruction of articular cartilage in tuberculous arthritis is not indicated. But when articular cartilage has already been destroyed, extension should lessen the tendency to erosion or invasion with sequestration of bone at the points of greatest pressure in the joint.

SURGERY

The Use of Plaster in the Treatment of Fractured Femurs.—W. M. Firor (*Bulletin of the Johns Hopkins Hospital,* December, 1924) undertook a comparison of results obtained by immediate immobilization in plaster of fractures of the shaft of the femur with those obtained by other methods of treatment. One hundred and two patients were treated by reduction and immediate application of a double plaster spica. The cases fell into the following groups: those treated by Buck's extension (average stay in hospital sixty-five days); those treated by overhead extension (fifty days); those treated by open reduction (fifty-seven days); those treated by *immediate* immobilization in plaster; and those treated by *early* immobilization in plaster (nineteen days; for patients over fourteen years, thirty-four days; between seven and fourteen years, fifteen days; and under seven years, fourteen days). The transition from one method to the other is described. The following conclusions are drawn: Immediate immobilization in plaster of fractures of the shaft of the femur does not give satisfactory results in patients over fourteen years of age, whereas in patients between seven and fourteen years, the method gives good results, and in children under seven years, this method gives results which are as good as those obtained by overhead traction. By the use of the method described as early immobilization in plaster, the period of residence in the hospital is greatly reduced.

Arthroplasty Upon the Temporomandibular Joint.—H. McWilliams (*Annals of Surgery,* April, 1924) says that a number of cases of ankylosis recur after operation, and he has classified the causes of these recurrences in three groups as follows: 1. Operations performed in cases that are still in the active stage of arthritis; 2, incomplete operations; 3, cases where either inadequate or no forms of excisors were used. In all cases, it is essential to use an excisor as a postoperative measure. It is advisable to remove most of the condyle. Any pressure made upon the teeth should be upon the canine or those posterior to the canine. It is nonessential to interpose any material between the divided bones. Injury to the occipital frontalis branch of the facial nerve frequently occurs. No touch technic should be employed.

Arthroplasty of the Knee.—W. C. Campbell (*Annals of Surgery,* July, 1924) refutes a statement of a previous report in which he found the results of arthroplasty discouraging, and now asserts that in well selected cases arthroplasty is justifiable and gives an excellent chance of attaining satisfactory motion. He describes the operation and aftertreatment in detail, laying special stress on the intelligent cooperation of the patient as regards the latter. As soon as the operation is completed the limb is placed in a Thomas splint, with a joint at the knee, and a hoop of steel connected just above the anterior to the knee joint. A rope is attached to the centre of the hoop and overhead to a simple wooden frame. A second rope is attached to the lower extremity of the Thomas brace, which passes directly upward to the wooden frame, through a series of pulleys, to the head of the bed, where it is attached. By adjusting these two, any desirable angle may be maintained and by gravity of the leg, under direct control of the patient, passive and active motion instituted. The limb is first placed in the extended position with moderate traction, except in patellofemoral fusion, when flexion is desirable. No motion is instituted until local reaction has subsided, which requires about eight or ten days. Active motion is encouraged with special attention to the development of function in the quadriceps. Passive motion is carried out by the patient, who is given the end of the rope, which is detached from the head of the bed, and by gravity of the leg flexion is made. The subject soon finds that considerable motion is possible without pain. The splint is removed in about six weeks, depending on the stability of the joint, and a simple overhead sling, with block and tackle, substituted, when walking on crutches is permitted. Weightbearing is gradually increased with care to avoid reaction. In resistent cases brisement forcé is of value, if cautiously employed, under nitrous monoxide, with full extension and only ten degrees increase in flexion on each occasion. The value of physiotherapy should not be underestimated, though by no means essential to success, if the measures above described are closely followed by the patient. Total disability is expected from two to three months, partial disability for six months, depending upon the occupation of the individual. Complete extension is essential; sixty to ninety degrees flexion gives the best functional results and a member which can be used for all practical purposes.

Surgery of Knee Joint.—P. H. Kreuscher (*Annals of Surgery,* July, 1924) states that the management of all knee joint injuries resolves itself into four distinct equations.

1. A proper diagnosis of the lesion made from the history of the case and physical and x ray examinations. A study of the mechanism of the accident and a thorough knowledge of the anatomy of the tissues involved are necessary to enable the surgeon to make his decision. The diagnosis by x ray should be made only from a stereoscopic picture.

2. The surgical procedure involves a careful reapposition of injured tissue whether it be osseous, cartilaginous or tendinous and if this is not feasible, a removal of that portion which cannot be utilized or is foreign to the joint and if necessary a substitution of bone or fibrous tissue from some other part of the body.

3. Operative measures upon a joint must be carried out with the strictest aseptic technic and at such time when nature's walling off or cofferdaming is complete. There is no longer any reasonable excuse for introducing into the joint the operator's finger, any instrument, appliance or sponge which is not absolutely sterile. The joint tissue is

as sensitive and as unprotected against infection as the eye and reacts badly to excessive manipulation or trauma.

4. The after care requires the use of such appliances as are necessary to hold the tissues in position. Active and passive motion must be sufficiently early to avoid excessive adhesions and not so late as to permit periarticular fixations to form. The application of physiotherapeutic measures, especially diathermy and heliotherapy, must be utilized to the fullest extent.

Surgery of Knee Joint.—N. Allison (*Surgery, Gynecology and Obstetrics,* October, 1924) points out the following facts: In many clinical conditions, a high percentage of disabled knees may be returned to normal knee joint function by appropriate surgical intervention. In certain disease processes, notably tuberculosis, operation upon the knee offers the one sure method of cure. Here the operation should have for its object the establishment of ankylosis. Until such time as the treatment of tuberculosis by heliotherapy has been perfected and made practical, this would seem to be the better position to hold. In certain disease processes, notably the acute infections of the knee, operations to clean the joint cavity, or to establish drainage, hold the only promise of conservation of knee joint function. Functional use of the lower extremity may be well carried out with a stiff, strong, weightbearing knee. Functional use of the lower extremity is inhibited or lost if the knee is insecure, painful, or partially functioning. The dangers that come with an insecure knee are not insignificant. The menace that shadows the life of an individual with a tuberculous knee is very real. It is possible by surgical measures to restore the lost function to a knee joint. It is also possible by surgery to aid nature in healing the diseased knee.

Habitual Dislocation of Patella.—W. E. Gallie and A. B. Lemesurier (*Journal of Bone and Joint Surgery,* July, 1924) offer the following operative technic as one which obtains perfect functional results and bars recurrence. It is based on the principle of anchoring the patella in place regardless of the original cause of the dislocation or of any anatomical peculiarities that may be present. It consists of tethering the patella by a strand of tendon or fascia to the internal condyle of the femur at the point which forms the centre of the circle through the arc of which the patella moves on flexion and extension of the knee. Transplants of tendon, when not too thick, and transplants of fascia live indefinitely and retain their characteristic structure and strength. It is only necessary, therefore, to make certain of solid union of the tendon or fascia to both the patella and the condyle to obtain the desired result.

The technic of operation varies with the force required to hold the patella in place. When such force is very great a thick piece of the tendo Achilles is used. For the ordinary type of habitual dislocation, however, a very moderate amount of force applied in the right direction is sufficient, i. e., the fascia lata.

The tethering of the patella is accomplished through three small incisions, one on each side of the patella and one over the most prominent point of the internal condyle. Two transverse holes are drilled through the patella about half an inch apart and two slightly larger holes are bored in the internal condyle as in the operation already described. A strip of fascia lata, ten inches long and half an inch wide, is then obtained through an incision on the outer side of the thigh and thoroughly scraped free of areolar tissue. A stout ligature is tied to each end to facilitate insertion. This strip is then passed through the holes in the patella so as to leave a loop at the outer side of the bone. The free ends are then drawn through a subcutaneous tunnel to the incision over the internal condyle. Here they are passed in opposite directions through the hole in the internal condyle so that they overlap each other both in the tunnel in the bone and an inch or more beyond it. The fascia is then drawn taut and the loop is completed by careful suturing with chromicized catgut. By this means the patella is tethered to the internal condyle by a loop of fascia which not only heals to itself in the portion which is overlapped but also to the bones through which it passes. In a few weeks the union is so solid that all possibility of a recurrence of the dislocation is removed.

The advantages which we see in the operation are several. In the first place it is simple, as the only incision of any size is that through which the strip of fascia is obtained. The gap left in the fascia lata is sutured and invariably heals without leaving symptoms or disability. There is none of the risk which attends osteotomy of the femur or any operation which necessitates the opening of the knee joint. The fixation is mechanically sound, as it is obtained by means of a band of very strong material which we know will remain permanently in place and retain its strength and form, and which is so placed that it will exert the necessary pull on the patella in the right direction in all positions of the joint. Finally, the operation is applicable to all cases of recurrent dislocation of the patella and can be relied upon to prevent outward displacement, no matter what the predisposing cause.

Astragalectomy.—W. R. MacAusland and A. R. MacAusland (*Annals of Surgery,* December, 1924) accept this as the operation of choice on account of the many good functional and cosmetic results obtained if it is properly performed. They emphasize the following points in the technic: Correct all existing deformities before open operation. Astragalectomy may be done with or without tendon transplantation, tendon fixation of the peroneals or transplantation through the Achilles and resuture, with strong displacement of the foot backward. Proper aftercare should be followed by the operator and not by untrained assistants. Recurrent deformity is due to improper postoperative care. Lack of posterior displacement is due to careless or improper operative technic, such as failure to remove head of astragalus.

Metal Pry Pin in Fractures.—J. S. Welch (*Surgery, Gynecology and Obstetrics,* December, 1924) describes a metal pry pin procedure useful in the reduction and control of fractures. Following are its points of value as enumerated by the author.

1. The reduction of fragments occurs under the more favorable fluoroscopic observation, rather than the method of taking röntgenograms before and after reduction.
2. The principles are simple.
3. The danger to already damaged soft tissue about the fragments, by too vigorous manipulation during attempted reduction in difficult cases is greatly lessened.
4. The feature of retention of fragments is most helpful in selected cases.
5. Considering the method an open operation, it reduces the same to the minimum risk as such.
6. The use of the pry pin in compound fractures is not necessarily contraindicated. The pin gives the added advantage of drainage.
7. No foreign body remains after ten to fourteen days, and no secondary operation is required.
8. No complications creditable to the pin per se have yet occurred.
9. Its limitations appear in the largest bones with strong contracting muscles, and where soft tissue intervenes between fragments, and where large vessels are too near, especially with preexisting hemorrhage of importance.

Foreign Bodies in Fractures.—E. D. Martin (*International Journal of Medicine and Surgery,* July, 1924) presents an operative technic for fractures of the neck of the femur, whose principle is the fixation of the head of the bone to the femur, rather than the femur to the head, at the same time allowing movement within a small radius, and yet not separating or mobilizing the fragments.

A radiograph is taken outlining the fracture, the nearer the trochanter the better the prognosis. An incision is then made over the prochanteric eminence, about six inches in length, the bone exposed and the finger passed over the trochanter, locating the neck and head; a hole the size of a No. 6, three and one half inch wood screw is drilled through the bone to the line of fracture. An assistant then pulls on the limb until both internal malleoli are in line, inverts the foot slightly and holds it in this position until the screws are inserted. A screw is then introduced and directed as far as possible in the line indicated by the finger; another picture is taken, and if this screw is found to be properly placed, the second is inserted about one inch below and in the same direction, sufficient force being applied to bring the fragments in close contact. You can easily see how readily this is done. The shaft of the screw is driven into the distal fragment; this acting as a nut, the opposing head or fragments are drawn together and in this way the two are closely and firmly held. This done, the head of the femur is now securely fastened to the shaft through the trochanter. The wound is closed with a small drain if the

patient is fat, and all that is now necessary is to place the limb in a Hodgen's splint or hammock until the wound heals, or even longer, if deemed advisable. At the end of four weeks the patient is allowed the freedom of the bed until such time as it is thought safe to allow the use of a roller chair or crutches.

The technic, if carried out as described, will give the results claimed in any case where the condition of the patient is such as to insure osteogenesis.

ANESTHESIA

Ether Anesthesia.—Ethel Ronzoni, Irene Koechig, and Emily P. Eaton (*Journal of Biological Chemistry*, September, 1924) state the following conclusions from their experimental work on the role of lactic acid in the acidosis of ether anesthesia: Accumulation of lactic acid accounts in large part for the acidosis of ether anesthesia. Its increase is independent of CO_2 tension and produces the changes in pH rather than being itself controlled by pH as stated by Anrep and Cannan. Decreased oxygen supply to tissues does not account for its production. The source of lactic acid seems to be the muscle tissues. Production of lactic acid in the muscle, together with loss of phosphate from the muscle (Stehle and Bourne), during anesthesia, points to a breakdown of some hexose phosphate such as Embden's lactacidogen.

Acidosis of Operative Anesthesia.—Alfred E. Koehler (*Journal of Biological Chemistry*, December, 1924) reports the changes observed in the acid-base balance during ether anesthesia induced by the closed cone method and operation. In all cases there was an acidosis ranging from blood pH 7.37 to 7.09. The available alkali of the blood, as measured by the total CO_2, decreased, but usually only slightly, and not at all comparable to the drop in pH had the latter been caused by nonvolatile acids. With the open drop method there was an increase in CO_2 tension of the venous blood in all cases, though the increased tension was very much greater in the closed cone than in the open drop method. This probably accounts for the milder acidosis in the cases done with the latter method.

Alleged Synergism of Magnesium Sulphate and Morphine When Injected Prior to the Induction of Anesthesia by the Ether-Oil Colonic Method.—Harry Beckman (*Journal of Laboratory and Clinical Medicine*, December, 1924) in view of the paucity of experimental data on which to base a belief in the synergism of magnesium sulphate and morphine, has conducted a series of experiments on dogs with the following results: one oz. of a mixture of seventy-five per cent. ether and twenty-five per cent. olive oil to twenty pounds of body weight, introduced into the colon of dogs one hour after the subcutaneous injection of one quarter c.c. of a four per cent. solution of morphine sulphate to the kilo of body weight, is effective in inducing safe and satisfactory surgical anesthesia and in maintaining it for a little more than one hour. One ounce of a mixture of seventy-five per cent. ether and twenty-five per cent. olive oil to forty pounds body weight, introduced into the colon of dogs one hour after the subcutaneous injection of one quarter c.c. of a four per cent. solution of morphine sulphate to the kilo of body weight and two c.c. of a fifty per cent. solution of magnesium sulphate, is not effective in inducing satisfactory surgical anesthesia. The subcutaneous injection of two c.c. of a fifty per cent. solution of magnesium sulphate at the same time that one quarter c.c. of a four per cent. morphine sulphate solution to the kilo of body weight is injected in dogs, when these injections are followed after one hour by the introduction into the colon of one ounce of a mixture of seventy-five per cent. ether and twenty-five per cent. olive oil to forty pounds of body weight, gives rise to undesirable respiratory symptoms and a general depression, which usually lasts two days. These symptoms are directly referable to the magnesium sulphate, because they do not arise when the salt is omitted, the other conditions being the same.

Splanchnic Anesthesia.—Of the three original methods—Wendling's, Braun's, and Kappis's—G. Labat (*Annals of Surgery*, August, 1924) recommends the Kappis technic with modifications. The best results are obtained when the solution is deposited between the semilunar ganglia and the renal pedicles. Variations exist in the inclination of the twelfth rib on the vertebral column which are responsible for a certain number of failures. These failures can be reduced to a minimum by applying the coefficient of correction of the costovertebral angle, that is puncturing on the lower border of the twelfth rib opposite the upper extremity of the first lumbar spinous process. It is perfectly safe to approach the splanchnic area from the back. By keeping close contact with the vertebral column and following the technic described for that route it is impossible to make an intraspinal or an intravenous injection. The concentration of the solution can be advantageously reduced from one per cent. to one half per cent.

Local Anesthesia of Abdominal Sympathetic System.—R. E. Farr (*Surgery, Gynecology and Obstetrics*, September, 1924) finds that local anesthesia possesses many advantages when applied to intraabdominal surgery. Many of the objections to its use are based upon its improper application. Anesthesia methods should be simplified as much as possible and the surgeon who essays the use of local anesthesia should possess appropriate equipment and sufficient training to enable him to administer his own anesthetic. The term "local anesthesia operation" should be used to signify only operations which are carried to their completion without curtailment and without pain or the addition of other drugs. With an exhibition of the appropriate technic, complete anesthesia may be painlessly established for the performance of a vast majority of abdominal operations. And finally, the consistent use of local anesthesia in this field demands adequate equipment and an adherence to fundamental principles, the most important of which are the psychic preparation of the patient, a painless induction of the anesthesia of the abdominal wall, elastic retraction, exposure which allows the establishment of intraperitoneal anesthesia and a surgical technic compatible with the best interests of the patient.

Sacral Nerve Block Anesthesia.—W. R. Meeker and A. J. Scholl (*Annals of Surgery*, November, 1924), have made extensive studies in this field, from which they ascertain that anesthesia of the sacral nerves is entirely satisfactory for most operations that are to be carried out in the field supplied by the sacral nerves. It entails practically no immediate or late risk for the patient, and has been proved efficient and satisfactory. A knowledge of the posterior surfaces of both normal and abnormal sacrums and contiguous bony prominences is necessary in order to employ sacral anesthesia successfully. Certain variations of the structure of the sacrum may influence the case of induction or the result of the anesthetic. The size of the sacral hiatus is variable. The normal sacrum is made up of five vertebra. The number of foramina to be injected varies with the number of segments. Palpation of the bony prominences gives the most accurate knowledge of the location of the sacral hiatus and foramina. The posterosuperior iliac spines are the most readily accessible bony prominences and they usually bear a constant relationship to lateral foramina.

In certain cases in which the operation is to be performed in a field supplied by the lower sacral nerves, a single injection of novocaine in the sacral hiatus is sufficient. In the majority of cases the lateral foramina and the contained nerves, as well as the sacral hiatus, were injected, inducing immediate anesthesia which is satisfactory in practically all cases. A one per cent. solution of novocaine, to which was added a small amount of epinephrin, was employed. Our experience has not indicated that the combination of other salts with the novocaine results in a more satisfactory anesthesia.

Sacral injections for therapeutic purposes were carried out in the treatment of nervous conditions, and a proportion of cases of sciatica were definitely improved, but they were of very little practical value in the treatment of urinary disorders such as incontinence and enuresis.

In obstetrical cases sacral anesthesia has proved satisfactory in reducing the perineal pain incident to the passage of the child, and it also permits a satisfactory relaxation of the perineal muscles, which greatly reduces the tendency to tear. Obstetrical operations and manipulations may be painlessly performed under this anesthesia.

Anesthesia of the sacral nerves has proved satisfactory for most surgical procedures on the pelvic floor and viscera. It is especially satisfactory in urologic cases. The mortality following operations on the bladder, prostate and rectum is markedly reduced in cases in which sacral anesthesia is employed. In urological surgery many patients are encountered having a reduced renal function. Sacral anesthesia, which in most cases does not increase the work of the kidneys, is especially desirable.

Cystoscopic examinations and urethral and bladder manipulations may be readily carried out under sacral anesthesia. Small contracted, infected and malignant bladders may be dilated sufficiently to make a complete, unhurried examination without discomfort to the patient. A single injection in the hiatus sacralis is sufficient for the majority of cystoscopic examinations and manipulations.

Undesirable complications and sequelæ are exceedingly rare following sacral anesthesia. In no case did any permanent or lasting trouble develop. Occasionally in debilitated patients slight toxic symptoms followed the injection of the novocaine epinephrin solution, but these readily passed off; in the majority of cases the patient was perfectly well following operation and had no ill effects from the anesthetic.

Sacral Anesthesia.—L. E. Moon (*American Journal of Surgery,* November, 1924) is convinced that sacral anesthesia is the method of choice for rectal operations when performed in a hospital, for the following reasons: First, the convalescent period is shortened; second, the number of postoperative complications is lessened; third, there are no anesthetic and postanesthetic dangers and complications; fourth, the depth and completeness of the anesthesia makes the operative procedure less difficult.

Anesthesia in Renal and Prostatic Surgery.—W. S. Pugh (*International Journal of Medicine and Surgery,* October, 1924) makes a study of regional anesthesia, with the following conclusions: 1, Regional anesthesia is indicated in all operations on the kidney, bladder and prostate. 2. It reduces shock as well as urinary and cardiac disturbances to a minimum. 3. With a little practice all of the technics are readily acquired. 4. Suprapubic operations may be done by one of several technics. 5. Perineal prostatectomy is best accomplished by a combined sacral and parasacral anesthesia. 6. In renal operations, paravertebral anesthesia is the method of choice. 7. Difficult cystoscopies and intravesical technics may be readily done under sacral anesthesia.

DIABETES

Hemosiderosis: a Case of Bronze Diabetes with Endocrine Disturbances.—P. L. Marsh (*Endocrinology,* November, 1924) gives a detailed report of a patient, observed for three months preceding death, who presented two distinct syndromes, bronze diabetes and eunuchoidism. The course of the former disease was striking and its progress, as evidenced by failing carbohydrate tolerance, was rapid. One variety only of pigment, hemosiderin, was found under the microscope, very abundant in the liver, heart, stomach, kidneys, bronchi, pituitary, thymus, and adrenal glands, testes, and skin. The question whether the disturbance was primarily a pluriglandular one could not be decided from the data at hand.

The Treatment of Diabetes.—Elliott P. Joslin (*Canadian Medical Association Journal,* September, 1924) in addition to a discussion of insulin gives the following directions for the treatment of the feet of diabetics over forty years of age in order to avoid gangrene, which, he says, with local infections, caused half the deaths from diabetes last year in the larger hospitals of Boston.

Hygiene of the Feet

1. Wash feet daily with soap and water. Dry thoroughly, especially between toes, using pressure rather than vigorous rubbing.

2. When thoroughly dry, rub well with hydrous lanolin as often as necessary to keep skin soft, supple and free from scales and dryness, but not enough to render feet tender. If nails are brittle and dry, soften by soaking in warm water half an hour each night and apply lanolin generously under and about nails and bandage loosely. Clean nails with orangewood sticks. Cut the nails only in a good light and after a bath, when the feet are very clean. Cut the nails straight across to avoid injury to the toes. If you go to a chiropodist, tell him you have diabetes.

3. Wear shoes which are large, broad and flexible and do not bind or rub. Wear new shoes half an hour only on the first day and increase one hour daily.

4. If the feet become too soft and tender, rub once a day with alcohol.

Treatment of Corns and Callosities

1. Wear shoes which cause no pressure. The Japanese seldom have gangrene. Beware of nails and torn linings in old shoes and wear new shoes for the first time in the evening. It is wise to have two pairs of shoes which differ slightly from one another and to wear them on successive days.

2. Soak foot in warm, soapy water; dry and rub with gauze, or file off dead skin. A corn may be painted with the following mixture: salicylic acid, one drachm; collodion, one ounce. Repeat for four nights; then, after soaking in warm water, the corn will come off easily.

3. Do not cut corns or callosities.

4. Wear pad to distribute pressure if necessary.

Circulatory Aids

1. Exercises. Bend the foot down and up as far as it will go six times. Describe a circle to the left with the foot six times and then to the right. Repeat morning, noon, and night. Rising on tiptoes twenty times is an excellent exercise.

2. If subject to chilblains, wash feet daily in warm water, dry carefully, and powder lightly with borated talcum powder, wear woollen stockings and avoid extremes of temperature.

3. Massage with lanolin.

4. Buerger gravity—hyperemia method for bed patients gives excellent results, as does the violet ray in indolent sores.

Treatment of Abrasions of the Skin

1. Insignificant injuries in the diabetic may result very seriously. Therefore, proper first aid treatment is of the utmost importance. Consult your physician.

2. Avoid strong irritating antiseptics, such as sulphonaphthol and iodine.

3. As soon as possible after injury certain surgeons recommend the application of sterile gauze saturated with medicated alcohol. Keep wet for one hour by pouring on more alcohol. Sterile gauze in sealed packets may be purchased at drug stores. Purchase a tube of boric acid ointment. Later keep wound covered with boric acid ointment on sterile gauze. Change daily until healed.

4. Elevate and, as much as possible until recovery, avoid using the foot.

5. Consult your doctor for any redness, pain, swelling, or other evidence of inflammation.

The Use of Intarvin Fat—Glyceryl Margarate—in Diabetes Mellitus.—Charles S. Keefer, William A. Perlzweig, and William S. McCann (*Bulletin of the Johns Hopkins Hospital,* September, 1924) report four cases of diabetes in which intarvin was substituted for the fat of the diet. One patient received intarvin with his diet for four days, and in the other cases only one day periods were used. In these patients there was a very definite diminution in the amount of acetone bodies excreted in the urine during the day on which the intarvin was fed, with the exception of one patient in whom there was a rise of acetone body excretion. This diminution was followed in two cases by a slight rise of acetone body excretion when the natural fats of the diet were resumed. In two cases this decreased acetone body excretion continued even after the resumption of the diet containing ordinary fats. In view of the results reported, it is quite probable, but not certain, that intarvin gives rise to less ketosis than does an equivalent amount of ordinary fat. From a practical point of view, the use of intarvin fat in diabetes is limited, because it is intensely disagreeable for the patient to whom it is given as the chief source of the fat.

Pitfalls in the Diagnosis of Diabetes.—Henry J. John (*American Journal of the Medical Sciences,* January, 1925) says that the finding of glycosuria alone is not a sufficient basis for the diagnosis of diabetes. If glycosuria is innocent then it is due to a low renal threshold or to an overflow of glucose as the result of a very heavy carbohydrate meal. On the other hand, if glycosuria is due to diabetes it is not innocent and therefore the presence of glycosuria should be considered an indication for the institution of such procedures as will determine its cause in the individual case. All that is required in such a case is to instruct the patient to eat a heavy carbohydrate meal and to present himself at the office exactly three hours thereafter for a blood sugar estimation and urine examination. If the individual is normal, there will be no hyperglycemia because, in a normal individual whose tolerance for carbohydrates is unimpaired, the blood sugar content will be normal or subnormal. On the other hand if at the end of the three hour postprandial

period the blood sugar is above the normal level, the patient is definitely a diabetic whether or not there be sugar in the urine. Thus, for diagnostic purposes, the three hour postprandial blood sugar estimation is of much more importance than the fasting blood sugar estimation.

The length of time since the last meal should always be considered when blood is taken for a general estimation since the blood sugar content varies during the day and a postprandial rise may be misinterpreted as a result. In the continued study of a case it is essential that the blood be taken always at the same periods with reference to meals, the test always beginning with a fascinating blood sugar estimation.

As has already been emphasized a fasting blood sugar estimation alone is not of diagnostic value, since in even a severe case of diabetes the blood sugar content may be normal if the patient is on a proper diet. Due to this very fact some cases have been misinterpreted in laboratories, where, since the fasting blood sugar was found to be normal and glycosuria not present, the patients were told that they did not have diabetes. As a result these patients returned a few months later in such an advanced stage of diabetes that the administration of insulin was required.

Paget's Osteitis Deformans with Diabetes Insipidus and Nervous and Endocrine Disturbances.—R. Schön (*Münchener medizinische Wochenschrift,* December 5, 1924) believes latent Paget's disease much more common than it has been thought to be, and ascribes to it many symptoms of nervous disorder capable of production by the mechanical effects of increased pressure on the part of a thickened skull. In the case reported headache, vertigo, and floating particles before the eyes first developed; then exophthalmos and diabetes insipidus appeared, the gait became unsteady, and a pituitary tumor was diagnosed by means of the x ray. Irregular menstruation indicated an involvement of the ovaries. Only in this later period did marked bony enlargement become manifest and rarefaction of numerous areas in the skull and long bones were detected.

Proteotherapy in Diabetes Mellitus.—M. Grossmann and J. Sandor (*Wiener klinische Wochenschrift,* August 28, 1924) report marked improvement of the metabolism in a number of cases of diabetes with the use of caseosan, usually given for a few days, even when insulin had no effect. Certain associated symptoms, especially neuritis, are favorably influenced. The excretion of acetone usually remains unaffected. The reduction of the glycosuria and of the blood sugar content is an indication for the suitability of the case for this type of treatment. The cases with nondiabetic complications are aggravated. Some are not influenced by the caseosan. Therefore proteotherapy has decided advantages in certain cases, which must be carefully tested as to their suitability for this treatment.

The Variability in Rabbits Used for the Assay of Insulin.—J. P. Rose and H. W. Acton (*Indian Medical Gazette,* July, 1924) describe their experiments and say: "In the different rabbits tested by insulin there was a variation in the reduction of the amount of blood sugar after the same dose. This variability is closely correlated to the color of the animal tested; the albinos are the least affected and the black and white have convulsive symptoms due to the hypoglycemia. Small doses of adrenalin inhibit the action of insulin by causing hyperglycemia. The adrenalin content can be markedly increased by fright and exercise. The color variations are closely associated with the adrenalin content in the blood of these animals."

Reduction of Human Blood Sugar by Means of Insulin.—S. H. Kahn (*Boston Medical and Surgical Journal,* July 24, 1924) says that the reduction of blood sugar in normal individuals at rest to the unit of insulin is strikingly similar. The blood sugar level is a factor in the amount of blood sugar reduction. The weight probably governs the duration of the effect of insulin. The variations in reduction of blood sugar in diabetics may be accounted for to a great extent by the amount of insulin used per kilo of body weight, by the blood sugar level, and the amount of available body sugar. Insulin produces a greater fall in the blood sugar of diabetics than in normals; the least fall in blood sugar of diebtics takes place in the patients whose blood sugar level approaches the normal, and may be as low as normal. The least reduction of blood sugar to the unit of insulin takes place in diabetic coma; the next lowest in precoma cases. The power of the body to restore the alkali reserve, marked cardiac failure and toxic goitres probably influence the action of insulin.

Effect of Insulin Upon the Reducing Substance in the Cerebrospinal Fluid of Normal Rabbits.—Michio Kasahara and Eikichi Uetani (*Journal of Biological Chemistry,* March, 1924) studied the effect of insulin on the spinal fluid sugar of normal rabbits. They found that after subcutaneous administration of insulin there was a decrease in the concentration of the reducing substance in the spinal fluid. There is probably in the cerebrospinal fluid and blood always some parallelism of the content of the reducing substance, and therefore its concentration in the fluid varies directly with the degree of glycemia.

Clinical Assaying of Insulin and the Insulin Requirement.—Constant assaying of numerous lots of insulin as received from the manufacturers convinced R. M. Wilder (*Endocrinology,* September, 1924) that the uniform results obtained are evidence of a direct action of insulin on glucose, a definite chemical interaction being manifest between insulin and glucose. He found that the glucose equivalent of insulin, however, may be altered by high protein and high carbohydrate diets, and the insulin requirement of the individual may be diminished by starvation. The glucose equivalent of insulin is also depressed by acute complications, especially by infections.

Studies of the Effect of Exercises in Diabetes.—Robert O. Loebel, David P. Barr, Edward Tolstoi, and Harold E. Himwich (*Journal of Biological Chemistry,* August, 1924) used phlorhizinized rabbits to study the response to exercise during the completely diabetic state. The investigation was undertaken to ascertain whether an animal which has lost the power of oxidizing carbohydrate retains the ability to form lactic acid, and also to determine if lactic acid may be formed in a completely phlorhizinized animal whose glycogen stores are minimal. It was necessary to use artificial means of causing vigorous muscular contractions, and strychnine was employed for this purpose. It was found that lactic acid may be formed in an animal which is unable to oxidize carbohydrate, and it also appears in a completely phlorhizinized animal whose glycogen stores have been reduced to a minimum.

Favorable Effects from the Alimentary Administration of Insulin.—R. Murlin, C. C. Sutter, R. S. Allen, and H. A. Piper report (*Endocrinology,* May, 1924) on experiments carried out in the endeavor to find a satisfactory method for the oral administration of insulin. They satisfied themselves that insulin in crude solution containing 0.1 per cent. of hydrochloric acid, when placed directly in the duodenum of the diabetic patient, can be absorbed and can function to cause the utilization of sugar. Also that insulin, in enteric coated tablets containing a substance designed to delay temporarily the destructive action of trypsin, can survive passage through the stomach in some patients, can be absorbed in the intestine, and can operate to improve the diabetic condition very materially.

Low Nitrogen Metabolism with Low Carbohydrate Diet in Diabetes.—Karl Petren (*Journal of Biological Chemistry,* September, 1924) has for years been treating grave diabetes with a diet very low in protein, poor also in carbohydrate (especially no bread or other farinaceous foods) but higher in fat. His tables show that in diabetic persons with a carbohydrate intake much below forty gm. a day, with liberal amounts of fat, a low nitrogen metabolism may be obtained over long periods. The results indicate that the sparing influence of fat on the quantity of metabolized nitrogen is greater than has been assumed. By a combination of the low protein, low carbohydrate, and high fat diets a lower nitrogen metabolism than hitherto reported by physiologists has been secured, and this even on a low caloric intake.

Eye Conditions in Diabetes as Influenced by Insulin.—Grafe (*Medizinische Klinik,* July 13, 1924) says the effect of insulin on the eye is directly the opposite of that of adrenalin. When coma renders the reaction of the organ sluggish or imperceptible, insulin causes it to become normal in a day or two by increasing the tension. Retinal lipemia disappears rapidly under its influence. Refractive and accommodative disturbances run a shorter course and are less likely to return after its administration. A thickened lens may decrease to normal size, if the cataract is diabetic and of recent growth. When operation is performed on diabetic cataract, it is far more likely to be successful when insulin has been given. Diabetic retinitis, on the contrary, shows no improvement under insulin treatment.

Medicolegal Notes.

DUTY TO INFORM PATIENT OF NECESSARY PROCEDURE

The Georgia Court of Appeals holds, Bryson v. Aven, 124 S. E., 553, that the relation of patient and physician is a confidential one, and where in curetting a womb it becomes necessary, in order to effect a successful result, to insert a pessary, a duty devolves upon the physician to inform the patient within a reasonable time of the use of the pessary, and direct her as to when it should be removed. A failure so to inform her is held to be a fraud on her, and if injury result therefrom to the patient, a cause of action accrues at the time of the discovery of the fraud, or when, by the exercise of due care, the fraud might have been discovered by her, and not from the date of the injury, or the date of the operation. In such a case it was held that the operation and the insertion of the pessary were not an invasion of a right, and no cause of action could accrue until the discovery of the fraud and the resulting injury. Where suit was filed by the patient against a physician more than two years after the operation, but within only about three months after the discovery of the alleged fraud, and where it was alleged in the petition that an injury to the plaintiff resulted in a miscarriage on account of the failure of the physician to inform her of the presence of the pessary in the womb, and as to when it should be removed, it was held that a cause of action was set out, and the suit was not barred by the statute of limitations.

RIGHT TO MEMBERSHIP IN MEDICAL SOCIETY

The West Virginia Supreme Court of Appeals holds, State v. Monongalia County Medical Soc., 124 S. E., 826, that one cannot by mandamus compel a medical society to restore him to membership therein, when the proof shows that he was not elected to membership in the manner prescribed by the societys by-laws, though the president and secretary of the society erroneously announced his election.

VALIDITY OF CONTRACTS CONDITIONED ON CURE

An action by a surgeon to recover the sum of $1,000 alleged to be the balance due him upon a contract with the defendant for operating upon the latter's sister was defended on the ground that the defendant had not made the contract sued on, and that the contract he did make with the plaintiff was conditioned upon the operation upon his sister being successful, and that she died as the result of it within a few days. He had already paid the plaintiff $500 of his fee, and he made his answer a cross complaint to recover this sum from the plaintiff. The plaintiff denied that the contract was conditional. From a judgment for defendant the plaintiff appealed.

The Arkansas Supreme Court says, in reversing this judgment and remanding the case for a new trial, Guild v. Whitlow, 257 S. W. 383, that special contracts with physicians or surgeons upon the principle of "no cure no pay" are generally held valid. They are conditional contracts, and there seems to be no reason why a physician may not enter into a contract whereby his right to compensation may be dependent upon his curing the patient entirely by treatment or by operating upon him.

PRIVILEGED COMMUNICATIONS RULE HELD NOT TO APPLY TO PUBLIC RECORDS

In a prosecution for murder the certified copy of a certificate of deceased's death was held by the Iowa Supreme Court to be admissible against the contention that it violated the rule protecting privileged communications, that rule having no application to public records, State v. Flory (Iowa), 199 N. W., 303. On this question the decisions of the various states are not harmonious.

PUNITIVE DAMAGES FOR GROSS NEGLIGENCE OR RECKLESSNESS

The Oregon Supreme Court holds Rennewanz v. Dean, 229 Pac., 372, that no only will punitive damages be allowed in an action where the evidence was sufficient to show a malicious desire on the part of the defendant to inflict injury upon the plaintiff, but the authorities are numerous that punitive damages will also be allowed where the defendant's conduct is reckless, as if he knew the danger impending to the plaintiff, but proceeded with manifest indifference to the result. Likewise such damages are awarded where the defendant is grossly negligent. It is held to be for the court to determine whether there is evidence to go to the jury upon the subject; and it is for the jury to determine the fact from the evidence, and its exclusive province to assess punitive damages if there is any actual damage to which the exemplary damages may be added.

Where there was testimony that after being treated by injections for hemorrhoidal tumors at defendant's office the plaintiff experienced a severe hemorrhage which compelled him, after being given some hypodermic injections and some pills, to lie on a couch in the defendant's office for more than 24 hours during which no steps were taken to arrest the hemorrhage, until he was too weak to stand alone, and so wasted by loss of blood that his wife hardly knew him, and he remained for about a month in a hospital, requiring surgical operations, it was held that it was for the jury to say whether the defendant's treatment of plaintiff was reckless or even grossly negligent.

ACTION FOR MALPRACTICE HELD BARRED BY RELEASE OF DISPUTED CLAIMS FOR INJURIES

The Illinois Appellate Court holds, Guth v. Vaughan, 231 Ill. App., 143, that where a physician was sued for malpractice in setting plaintiff's leg, broken in an automobile collision, the action was barred by a release given by the plaintiff to the owner of the automobile acknowledging a sum of money received "to be in full accord and satisfaction of a disputed claim growing out of bodily injuries" sustained by him and releasing and discharging such owner "from any and all actions, cause or causes of actions, claims and demands, for, upon, or by reason of any damage, loss, injury or suffering" which he had suffered or would suffer "in consequence of such accident and injury," since he could not recover again for the same injury or its aggravation by malpractice.

CHARITABLE HOSPITAL NOT LIABLE TO PAY PATIENT FOR NEGLIGENCE OF NURSE

The Indiana Supreme Court holds, St. Vincent's Hospital v. Stine, 144 N. E., 537, that a hospital, organized under Acts 1881, c. 113 (Rev. St., 1881, §3502), without corporate stock, paying no dividends and not operated for profit, the money received from pay patients going into the common fund available to pay the expenses of both destitute and pay patients, is not liable for the negligence of a nurse to a pay patient, unless it appears that the corporation was negligent in selecting the nurse. The court finds that this is in accordance with the rule followed by at least twenty of the states and in the federal courts, and that in only three states, Rhode Island, Alabama and Minnesota, have the courts held the contrary. In Rhode Island, after the decision holding such corporations liable, the Legislature changed the rule by statute, leaving only two states holding the contrary doctrine.

Chronic Carbon Monoxide Poisoning an Increasing Danger to Municipalities from Automobile Traffic

EDWARD A. SHUMWAY, M.D.
Philadelphia

The subject of intoxication from carbon monoxide is not new, as is attested by the ever increasing literature on the subject, not only in medical journals, but in the daily press, and in popular and scientific magazines. A valuable monograph, which covers the subject in the fullest detail, appeared in Germany in 1920 by Prof. Louis Lewin, (1) and little new can be added to what has long been known of the clinical symptoms and pathology of the various types of poisoning which the gas produces in the human race. Lewin found a reference to the danger from the gas in Aristotle's writings in which he says, "that men suffer from heaviness of the head, and often die from coal gas"—a statement that must date from more than 300 years B. C. He also quotes from Valerius Maximus (2) the following, "Hannibal forced the inhabitants of Nuceria, each with two suits to leave the city, whereupon he prepared baths, and caused the people to be suffocated in them by steam and smoke," showing that this method of putting people to death was known fully 200 years B. C. The use of carbon monoxide gas for poisoning, either self inflicted or with murderous intent, by open charcoal or coal grates, has been frequently employed many times in the centuries which have elapsed, and in the form of illuminating gas is still one of the most common methods for committing suicide both in this and in European countries. The gas is formed wherever combustion of carbon containing material occurs, and as Sayers (3) says, "Carbon monoxide poisoning is one of the most widely distributed and most frequent of industrial accidents. The gas is a product of incomplete combustion and is without color, odor, or taste; therefore, its presence is frequently unsuspected in many places where it exists. It is an ever present danger about blast and coke furnaces and foundries. It may be found in a building having a leaky furnace or chimney, or a gas stove without flue connection, such as a tenement, tailor shop, or boarding house. Hospitals receive a great number of victims of poisoning, whether by accident or in an attempt at suicide, from artificial illuminating gas. Persons may be affected by leaks wherever water gas is formed or used. The exhaust gases of gasoline automobiles contain from four to twelve per cent. of carbon monoxide, and in closed garages men are not infrequently found dead beside a running motor. A similar danger may arise from gasoline engines in launches. The gas is formed also in stokerooms, in gun turrets on battleships, in petroleum refineries, and in the Leblanc soda process in cement and brick plants. In underground work carbon monoxide may appear as the result of shot firing, mine explosions, or mine fires, or in tunnels from automobile exhausts or from coal or oil burning locomotives."

The pathology of the action of the poison was for a time disputed, but it is now generally recognized that the deleterious effects of the gas in the human economy is due to the formation of a comparatively stable compound, by the union of the monoxide with the hemoglobin of the blood, for which it has an affinity three hundred times greater than does oxygen. Because of this, even when only a small amount of the poisonous gas is present in the air and breathed into the lungs, much of the hemoglobin is locked up in combination with carbon monoxide, and so can not keep up its usual work carrying oxygen to the tissues. The result is a withdrawal of nutrition, and if the action is sustained sufficiently long, the damage to the tissue cells becomes permanent, even if the patient survives.

The symptoms of acute poisoning from the gas have long been known and are summarized well by Sayers as follows: "The victim of acute carbon monoxide poisoning usually experiences the following symptoms: Yawning, sleepiness, weariness, and a feeling of constriction across the forehead; frontal headache, at first dull and intermittent, later continuous and more severe; this headache is replaced or masked by the typical headache of carbon monoxide poisoning, at the base and back of the skull, which causes the sufferer to hold his head as far back as possible in an effort to obtain relief; dizziness, nausea, and lassitude also occur. The pulse is at first normal, but later becomes full and rapid, the skin is flushed, the respiration becomes more rapid as exposure to the gas continues, and later becomes irregular. If the exposure is sufficiently long, or the concentration of carbon monoxide is sufficiently great, confusion and unconsciousness develop. As the victim recovers, he remains weak for some time.

Copyright, 1925, by A. R. Elliott Publishing Company.

The weakness persists especially in the muscles of his legs. A headache, sometimes severe, confusion, and partial loss of memory accompany recovery, but pass off in time. The nausea may be sufficient to produce vomiting. All the symptoms are accentuated by exercise, eating, and stimulants. When a person is overcome by large concentrations, the symptoms follow each other rapidly and he may fall quickly unconscious. The rate at which a person is overcome and the sequence in which the symptoms appear depend on several factors, viz., the concentration of the gas; the extent of physical exertion; the state of his health and individual predisposition; and the temperature, humidity, and air movement to which he is exposed. Exercise, high temperature, and great humidity, with no air movement, tend to increase respiration and heart rate, and consequently, result in more rapid absorption of carbon monoxide." Fatal accidents from the gas have multiplied in recent years from the enormous increase in the automobile output, and the careless running of engines in closed garages, and are constantly recorded in the daily newspapers. While there are other gases in the exhaust from the automobile, they are of no importance, from the viewpoint of toxicity, and the great danger in such accidents is the sudden loss of power of locomotion, which prevents the escape of the victim from the garage before he is conscious of any dangerous symptoms. The present efficient head of the Department of Public Health, of Philadelphia, Dr. Wilmer Krusen, has issued three important bulletins during the past year on the subject, so that it should be thoroughly known to every one, both physician and layman.

It is, however, to a less well known form of the poisoning that I wish especially to call attention, because it does not seem to have been sufficiently emphasized, and because in conversation with some of our best known clinicians, I have found a lack of knowledge of its occurrence. This is the chronic type of poisoning. It was brought to my attention by a number of cases in my own work as a specialist, a few of which may be briefly summarized as follows:

Case I.—A woman, forty-eight years of age, sought relief from headaches, two years ago. She had been the rounds of physicians, and had been ordered glasses by a competent Philadelphia oculist. She complained of burning of lids, or nervousness, and was ordered a change of glasses. Further study of the case revealed that she had suffered from repeated fainting spells, with loss of consciousness, and alarmingly weak heart action, with weakness of arms and legs; in one of the attacks she nearly died after three fainting attacks, before she was carried out of her apartment on to the porch. Fresh air always revived her, but her health became steadily worse, headaches were nearly constant; appetite vanished, and she suffered from vertigo; anemia became more and more pronounced, until she showed a gray color of both skin and lips. Investigation showed a bad furnace flue and the constant presence in the apartments of coal gas, as shown by the rapid clouding of lime water, when placed in pans on the floor. In summer the symptoms continued because she lived in the first floor of an apartment on West Walnut Street, and the fumes from the constant streams of passing automobiles were drawn into the rooms through the open windows. After removal from this apartment to a quieter locality, where the furnace flue was in better condition, she gradually recovered, had no further fainting spells, and the anemia was slowly disappearing.

Cases II and III.—A man and wife consulted me in June, 1922, referred by Dr. E. W. Kelsey, both complaining of severe headaches. Both had been the rounds for glasses and treatment of nose and throat conditions. The wife wore a belt for relaxed stomach, and the husband was told he needed an operation for appendicitis. Neither could do sustained eye work; both complained of nausea, vertigo and lack of appetite. Both needed glasses, which relieved them somewhat, but questioning showed that their symptoms were always more pronounced in winter, and it was found that they lived over a motorcycle store, and that machines were tested in the cellar of the building, over which there was no suitable ceiling to prevent the fumes of the gas from penetrating the apartments above. It was then recognized that they were suffering from chronic carbon monoxide poisoning. When the windows were open in summer, the air was sufficiently pure to cause no symptoms, but the latter immediately appeared with the cooler weather when the windows were shut.

Two of the best known pediatrists in the city, further, patients of mine, suffered from headaches, one especially from redness of the lids and watering of the eyes, and both from lack of appetite. Eye strain was removed, but symptoms persisted; one of them collapsed, as he entered a hospital door, when making a visit, and in both instances the trouble was found to be due to defective exhausts in the closed cars, which they were driving.

Finally, a prominent physician on North Broad Street, who had had to abandon his sleeping room in the front of the house, because of the disagreeable odors from the exhaust gas on the street, and had even found it necessary to cover his face in a back room, to get relief, arose one morning last summer and had an attack of nausea with dizziness, which compelled him to return to bed. This dizziness forced him to remain in bed for five days, and prevented a return to his office for three weeks. After four months, he writes me, he still feels the depressing effects; he becomes nauseated at once if he passes a car which is emitting heavy fumes, and will have to sell his house and move to another locality.

The effect on the traffic policemen at busy places is also well known. Dr. Hubley Owen, chief police surgeon, writes me that they "have numerous complaints from the traffic policemen, especially in the centre of the city, of headache and nausea at the end of the day's work. This is especially true in the summer, along Delaware Avenue, when the men are detailed regulating automobile traffic across the ferries.

"The foot traffic patrolmen complain of gastric disorders more frequently than the men from the districts. In many cases, these symptoms have actually been so persistent that I have sent them to the hospital for gastrointestinal x ray study and gastric analysis. I find that these studies are negative, and that after the men have had a few days' rest from

their traffic duties, their symptoms have been relieved."

It is equally well known that in many large garages, especially where repair work is done, on the upper floors, that many of the employees go home daily with severe headaches, and are oftentimes nauseated after a day's work.

The most common symptoms, aside from the headache and nausea, are dizziness, palpitation of the heart, general fatigue, lack of mental concentration; sometimes neuralgic pains; temporary amblyopia, which occasionally becomes permanent as a result of retrobulbar neuritis, ocular palsies, congestion of the the mucous membranes of the nose and throat and eyes, with dryness of the throat, irritation and watering of the eyes. Finally changes in the mental state may occur; loss of will power, lack of decision, restlessness and irritability on the slightest discomfort, insomnia and at times visual hallucinations. Dr. W. H. Wilmer (4) of Washington read an illuminating paper on the subject before the Section on Ophthalmology of the College of Physicians in this city in October, 1920, detailing the history of a family, all of whom, including servants, were affected by gas from a defective heater, and had hallucinations of vision and hearing. One child had visual defects, due apparently to optic neuritis. Ultimately the prolonged effect of the poison results in marked anemia, the patients presenting a gray, or yellowish color, and the blood count sometimes showing a reduction in the red cells to as low as 1,500,000 to the c. m., although no destruction of the corpuscles has been reported. General muscular asthenia at times results, and edema of the tissues, especially of the lower extremities, with disturbances of sensation and atrophic skin and muscle changes.

The condition of the air in the large cities, especially in the canyonlike thoroughfares of the central districts, is one which may well give thought to physician and sanitarian, and question as to the future. At times to a normal individual the gasladen atmosphere during heavy afternoon traffic is very trying, and to those previously affected by an acute poisoning by carbon monoxide, difficult to breathe. Many examinations of the air in New York Gity have been made, especially under the direction of Professor Yandell Henderson of Yale University, to whom we owe many valuable papers. His work was done in connection with calculations of the amount of carbon monoxide which can be safely breathed, in drawing up plans for the construction of the vehicular tunnel connecting New York city with New Jersey. He has shown that the exhaust gases of gasoline automobiles contain from four to twelve per cent of carbon monoxide, and experiments with an automobile in a closed building having shown that the engine discharges approximately one and five tenths cubic feet of carbon monoxide a minute. He likewise has shown when the time of exposure in hours multiplied by the concentration of carbon monoxide in parts per ten thousand of air equals nine, headache and nausea are induced, and when it equals fifteen or more, the conditions are dangerous to life. Moreover, if the volume of breathing is increased by exercise, (even by slow walking) the rate of absorption of carbon monoxide is increased proportionately.

In New York city, observations show that during moderate traffic, and on clear windy days, the conditions in the streets are on the average such as to imply no appreciable health hazard. When the traffic is congested, however, the air especially back of the large omnibuses is badly contaminated, and a source of danger. The problem, is, therefore, already an important one, and is likely to become more vexing as time goes on.

Prof. Henderson and Dr. W. H. Haggard (5) have made one excellent practical suggestion, that the exhausts of all closed cars, which constitute a large proportion of the vehicles now used, should be carried vertically up the back of the car, so that the gases may be discharged upward, and thus out of the respiratory zone of street air. As they justly remark, "the exhaust gases from automobile engines, are far more toxic than the smoke from the chimneys of dwelling houses, or from the smoke stack of most factories, or the funnels of locomotives. In amount the total volume of exhaust gas discharged in some single streets is not less than that from a large factory or power plant. For the smoke from dwelling houses and factory furnace chimneys are provided, and indeed required by law, to discharge as high into the upper air as possible. Experiments have shown that no appreciable loss of power results when the automobile exhaust is so arranged, and that there is nothing impracticable in so equipping trucks, omnibuses and closed passenger cars. The exhaust gas has about the same specific gravity as air of the same temperature, but being extremely hot, it is much lighter than street air, and if started upward above the level of pedestrians' heads, it would rise and escape out of the street and over the roofs, like a puff of smoke. Moreover, as most of the air which enters buildings passes through the doors, windows and gratings of the lower floor, while through the upper windows the draft is usually outward, except when there is a strong wind outdoors, the air entering the buildings would be less contaminated, where the gases started upward at a higher level. Further experiments in public garages made by Henderson, have shown that the problem of ventilation is a much simpler problem with the vertical exhaust, and the fire hazard is also reduced, as gasoline spilled on the floor can not be ignited by the vertical exhaust. With the horizontal exhaust the entire air of the garage is rapidly mixed with the gas, and adequate ventilation of garages is at present virtually not feasible." This seems to be the only practical method of offering much relief from air contamination. Full study of other remedies, such as hose connections to the exhausts of cars in garages, gas mask canisters on the exhausts and similar suggestions, have for one reason or another proved not practicable.

They suggest that legally the remedy could be applied by the state licensing authorities charging an additional ten dollars to twenty-five dollars a year on all cars using a horizontal exhaust. If such a bill were passed by the state legislatures, the car manufacturers would soon be compelled to make the necessary changes.

For garages the authorities should insist on proper ventilation, and so far as possible insist that repair shops should not be on the second floor, unless the ceilings are impermeable, and no openings should be allowed from the lower floors. The present require-

ments as to garages under private dwellings or apartments in the city of Philadelphia, which have been furnished me by Mr. Edwin Clark, chief of the Bureau of Building Inspection, are as follows: Garages may only be erected in the basement of one or two family dwellings. In the case of two family dwellings, it is permissible to have a basement partitioned off, so as to provide separate garage space for two cars. Basement garages are not permitted in apartment or tenement houses housing more than two families. When a basement is used for this purpose however, the walls and ceilings must be constructed of fire proof material, and the only openings into such basement garages must be from the outside of the building. No opening is permitted from the garage itself leading to the house above, nor to the cellar. Such requirements seem to be entirely satisfactory, and obtain also in Montgomery County, although architects do not always so arrange the construction. The general lack of information on the subject is responsible for the fact that the law is sometimes violated, because of the inconvenience of going outside the house to enter the garage, and health considerations are neglected.

The subject of poisoning from coal gas in houses and apartments from defective flues is also of great importance, and the great danger of cleaning out flues without letting furnace fires go out should be recognized. A case of acute poisoning recently studied by Dr. Fred Hartmann, Dr. Theodore Weisenburg and myself, which may result in permanent motor and sensory disturbances, is fresh in my mind, but in the present discussion, this topic is not germane.

Finally, before closing I desire to call attention to the added danger from the unnecessary running of automobile engines while standing on the city highways. Few large trucks are provided with self starters, and in cold weather, with the stiffening of the lubricating oils, cranking is physically difficult, so the drivers of such trucks frequently allow their engines to idle while loading, or unloading. The same is true of practically all the taxicabs in the city. The two chief companies here run approximately twenty-five hundred cars, none of which are provided with generators or selfstarters. At many cab stands from three to five cars will be found idling, despite the rules of the companies, because it is too much trouble for the men to crank their engines. In ordinary open city streets, when traffic is not heavy, this is not of so much danger. Where, however, as at the principal railroad stations, the space is confined, the accumulation of gas is very pronounced. At Broad Street station of the Pennsylvania Railroad from eight to ten cars run constantly, the air is foul, and is drawn into the station itself, and upward into the waiting room. At the West Philadelphia station usually twelve to fifteen cars are found running on an average. Inquiry of the starter from the cab company at this location revealed the fact that he goes home almost daily with headaches and nausea and lack of appetite, which his doctor can not relieve. In winter the effect on the ticket sellers inside is not pronounced, but I am told that in warm weather, when the doors are opened, many of them suffer perfectly typical symptoms of chronic carbon monoxide poisoning. This is a matter which could be readily controlled, it seems to me, by an ordinance in councils prohibiting unnecessary idling, or limiting the number of cars which can be thus running at any one cab station, and fining the companies where this number is exceeded.

This paper is rather desultory and presents no new facts, perhaps, but if it serves to impress upon the general practitioner the importance of going into the living conditions of his patients, and making inquiries as to the possibility of chronic poisoning by carbon monoxide in those suffering from headache, gastrointestinal disturbances, anemia, lowered nutrition and neurasthenia, my purpose will have been served.

Hay Fever Pollens in the Upper Air

Records Established by Airplane Flights

WILLIAM SCHEPPEGRELL, A.M., M.D.
New Orleans, Louisiana

OBJECTS OF POLLEN DENSITY TESTS

The general area that may be affected by hay fever plants and trees is an important factor in the etiology and prevention of hay fever and seasonal asthma. In immunological methods against these diseases, it is important to determine the pollens that are responsible for the attacks in the patient under treatment, and this requires not only a botanical survey of the surrounding territory, but also a knowledge of the distances that pollens may be carried under favorable conditions (1). If measures for control of hay fever plants are undertaken, the potential area of their pollen must also be known in order to determine the distance to which the weeds must be controlled. In both of these cases, the altitude that the pollens may attain is an important factor.

With a view of ascertaining these altitudes, an initial series of airplane tests was arranged by the American Hay Fever Prevention Association in the fall of 1923. These test flights were conducted under the direction of Mr. B. R. Coad, of the United States Department of Agriculture, at Tallulah, La., the exposed plates being sent to our New Orleans laboratory for inspection and recording.

These tests were carefully planned, preliminary flights being first made in order to ascertain the best material to be used on the exposed plates, and the length of time that these should be exposed at the various elevations. An exposure of twenty minutes was found to be the most effective, as a shorter time

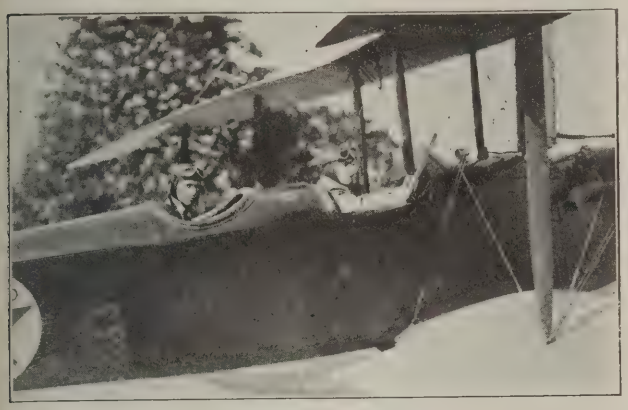

FIG. 1.—Standard airplane from which tests of hay fever pollen density in the upper air at New Orleans were made.

failed to furnish sufficient pollen to establish definite results, and a longer exposure resulted in the drying of the film by the rapidly passing air currents, and the consequent loss of the deposited pollens.

RAGWEED POLLEN CLOUDS

This series of tests established the fact that airplanes furnish a practical method of testing hay fever pollen density in the upper air. The records of these proved that the ragweed pollens, which are the most common in the air in the fall, when the first tests were made, are found in large numbers in the air up to the altitude of four thousand feet, and in diminished numbers as high as six thousand feet. Above this altitude up to fifteen thousand feet, which was the limit of the first series of flights, the pollens were also present but comparatively few in number (2).

Unless precipitated by rain, the clouds of ragweed pollens remain in the air practically during the whole pollinating season of these weeds, the fallen pollen being replaced by new pollen brought up by ascending air currents. The existence of these pollen clouds, and their gradual descent due to the cessation of ascending currents, explain the increase of hay fever pollen after sunset and during the prevalence of cold winds, both of which are associated with aggravation of hay fever attacks.

SPRING HAY FEVER POLLENS

As the initial series of airplane flights was made in the fall, it was decided to make an additional series of tests, the planes being again under the direction of Mr. B. R. Coad of the United States Department of Agriculture. The lowest altitude that was tested is the "hedge hopper," in which the airplane flies at as low a level as permitted by the trees and hedges. The greatest altitude attained in this series was seventeen thousand and nineteen thousand feet, respectively. All tests over ten thousand feet are made under considerable personal discomfort, as the cold is intense in spite of the special clothes and gloves worn by the observer and the pilot.

As in the previous series of flights, each exposure was made for twenty minutes, the plates being placed in a special holder, and afterwards sealed and sent to our New Orleans laboratory for examination. The speed of the airplanes averaged about eighty miles an hour. As the result of our experience in the first series of tests, the first exposure was made at each lower level of two thousand feet. At the same time, another airplane made tests at the intervening two thousand feet, so that records were made at each thousand feet levels in these tests.

The record of the airplane tests of the pollen density of the series of flights from May, 1924, to September, 1924, follows:

VARIATIONS OF HAY FEVER POLLEN DENSITY

The presence of these large numbers of pollens in the upper air show that, on account of their buoyancy, they are conveyed upward by the ascending air currents until the convective currents cease to be active. Unless precipitated by rain, the pollen clouds may remain for a time in a state of equilibrium. The distance to which they will then be carried horizontally in their descent will depend upon the velocity of the wind, and may be calculated by multiplying

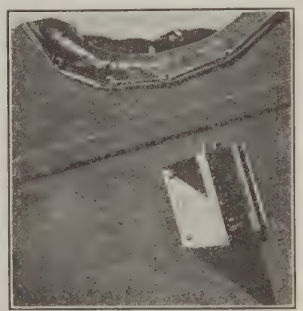

FIG. 2.—Special holder used on the DeHaviland 4 B airplanes for testing pollen density at Tallulah, Louisiana.

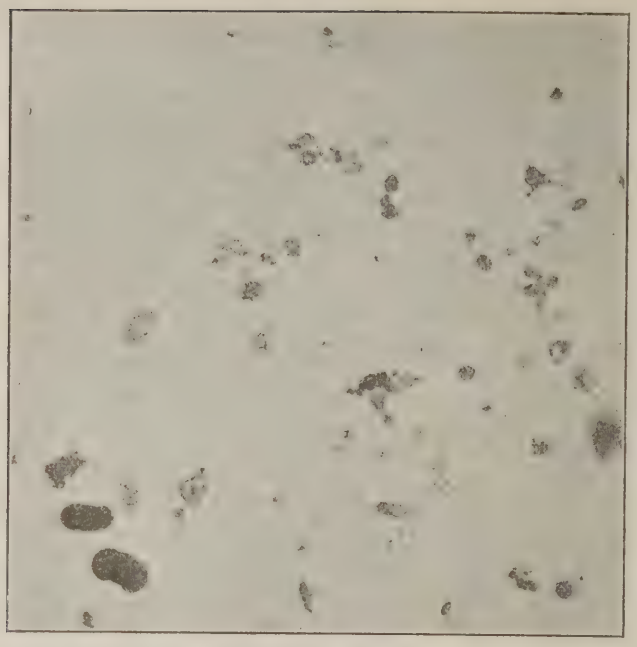

Fig. 4.—Photomicrograph of pollen plate exposed at two thousand feet elevation in New Orleans, March 10, 1925, showing pine grass, and dock pollens. x 200 diameter.

the velocity of the wind by the time of the fall (3).

These records illustrate the various changes in pollen density in the upper air, as influenced by seasons and meteorological conditions. In the test of May 19th, while the grass pollens were fairly common, the tree pollens formed the most important factor in the pollen density. No ragweed pollens were found in this test, as these do not begin to be produced until August, as evidenced in the record of August 16th and 17th, in which the ragweed pollens were found in small numbers to about three thousand feet, the grass pollen in diminished numbers, and a low record all pollens generally. By September 8th, however, the ragweed pollens became much more numerous, but there was a sharp fall in the density at two thousand and three thousand feet, differing in this respect from the records of the tests made September 15th and September 29th and 30th.

Fig. 3.—Photomicrograph of pollen plate exposed at two thousand feet elevation, at Tallulah, Louisiana, showing tree and grass pollens. x 200 diameter. (*Reduced one quarter.*)

On September 30th, which is the height of the hay fever season in the Southern States, the record of the ragweed pollen density was very high, there being almost twelve thousand pollens on the four plates exposed up to an altitude of three thousand feet. At four thousand feet, however, there was a sharp fall in the density.

The records of the exposed pollen plates vary at different altitudes and locations, showing that the pollen clouds change their position and density in accordance with the variations of the air currents of the traversed territory. These vary constantly, as shown by the behavior of airplanes over terrain of various characters. Vertical air currents of various velocities are constantly encountered, so that it is necessary to compensate almost continuously for them in operating the control of the plane. This is more noticeable at the lower elevations. In flying over New Orleans, for instance, at an elevation of one thousand feet, there is considerable roughness in the airplane, while at three thousand and four thousand feet, the sailing may be quite smooth. These conditions tend to change, moreover, as the day progresses, and as different objects absorb or radiate additional heat.

AIRPLANE POLLEN TESTS AT NEW ORLEANS

As all the series of tests were made in the northern part of Louisiana, it was decided to make a check test at New Orleans in order to ascertain the influence of conditions due to a large city in which most of the area is covered by streets and residences, and with a relatively smaller number of plants and trees distributing the pollen. New Orleans has the Gulf of Mexico to the Southeast and Lake Pontchatrain to the North, and the influence of these bodies of water also required investigation. With a view of testing these conditions, the author made an air-

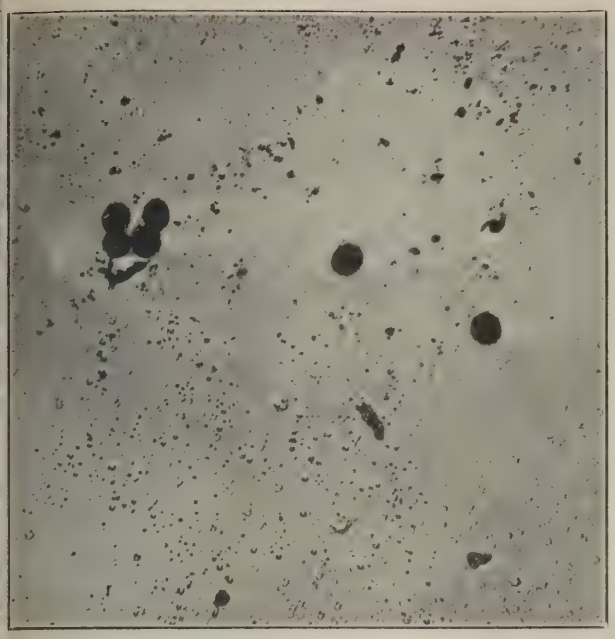

FIG. 6.—Photomicrograph of pollen plate exposed at five thousand feet elevation at Tallulah, Louisiana, September 15th, showing ragweed pollens. x200 diameter.

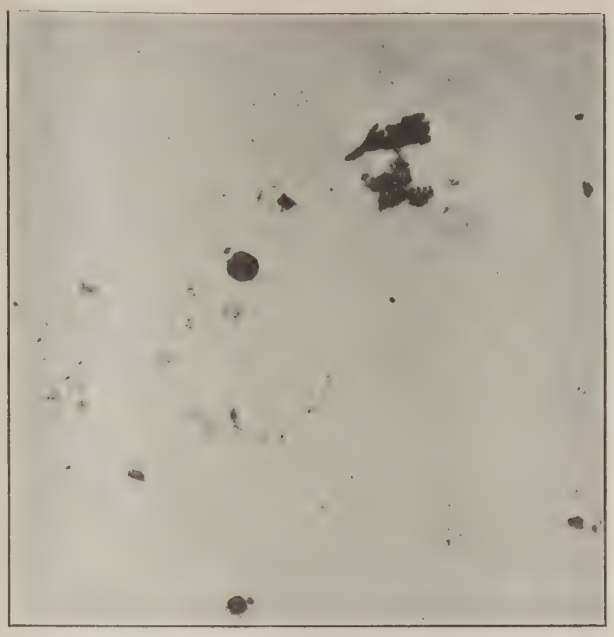

FIG. 7.—Photomicrograph of pollen plate exposed at ten thousand feet at Tallulah, Louisiana, showing ragweed pollens, September 29th. x 200 diameter.

plane test at New Orleans on March 10, 1925. The record of this follows:

Altitude	*Grasses*	*Rumex*	*Cedars*	*Pine*	*Other Pollens Prin. of trees*	*Total*
1000 ft.	976	59	114	72	2416	3637
2000	328	22	65	17	636	1068
3000	169	9	17	3	163	361

This test was made five weeks earlier in the season than the one of May, 1924, at Tallulah, but also demonstrates the larger number of tree pollens which are found in the upper air in the spring season. The noteworthy feature, however, is that while the tree and grass pollens were found at Tallulah with little diminution up to three thousand feet, there was a sharp fall in New Orleans after the first thousand feet, and comparatively few at three thousand feet.

The difference in these records is evidently due to the large area covered by residences and streets in New Orleans, and the large area of surrounding water. As comparatively few pollens arise from this area, the pollens found are evidently descending from pollen clouds formed in the surrounding territory, which explains their lower level.

CONCLUSIONS

These series of airplane tests demonstrate that hay fever pollens are commonly found in large numbers up to high altitudes during the pollinating season of the plants and trees which produce them. The distance that they traverse in their descent may therefore be five to ten miles, according to the variety of pollen in the air, and in the botanical survey to ascertain the incriminating pollens of any special locality, this must therefore be taken into consideration.

The presence of the pollen clouds, and their change of position, not only by winds but also by ascending and descending air currents, explain many of the phenomena associated with hay fever, such as the aggravation of the attacks after sunset and during cold changes in the midst of the hay fever season.

The extensive potential area of hay fever pollens, as demonstrated by the airplane tests of the density in the upper air, also shows that the effective control of hay fever by the enactment of municipal antiweed ordinances is insufficient. While such laws are of undoubted assistance, complete relief can be obtained only by legislative cooperation of the various States and of the Federal Government. The facts as demonstrated in this report indicate the need of such legislation.

Studies in Pollen Sensitiveness

I. S. KAHN, M.D.,
and EMMA M. GROTHAUS, Technician
San Antonio, Texas

The deductions in this article are based, first, on almost daily examinations of the pollen content of the air over a period of almost two years. Specimens were taken in both the residence and business districts of San Antonio, and also for comparison, from several of our neighboring cities and towns. A previous article may be referred to for a discussion of the botanical aspects of this study (1).

Secondly, the conclusions clinically are based on an intensive study for three years of over two hundred and fifty cases of pollen hay fever and asthma, principally of perennial chronic asthma, the form of pollen allergy most commonly met with in this section. The history of the duration of the patient's symptoms, coincident with the appearance and duration in the air of hay fever or asthma reacting pollen, along with the exhibition of cutaneous irritability in the form of the usual reactions as provoked by the intradermal tests to such pollen, were assumed to make the diagnostic connection complete, especially when it was possible to secure the prevention or abatement of the usual symptoms by the use of the pollen precautions to be mentioned or treatment with extracts of the pollen or pollens in the air and giving indubitably positive skin tests.

In San Antonio and vicinity we have four active important antigenic pollen factors, each with a definite pollination season: winter, the grasses (Gramineæ and mountain cedar (Juniperus sabinoides); spring, the grasses (Gramineæ); summer the grasses (Gramineæ), carelessweed (Amaranthus blitoides) and fall the grasses (Gramineæ), carelessweed (Amaranthus blitoides) and ragweed (Ambrosia trifida). In early spring, our pollen plates are also loaded with tree pollen, chiefly live oak and hackberry, but only the grasses seem of clinical importance. The chenopods (Chenopodiaceæ), sages (Artemisias) and Russian thistle (Salsola pestifer) are not factors in this vicinity.

Patients may be sensitive to any combination of these causal factors, so that with us simple pollen hay fever is frequently perennial, or almost so. In addition, it will be noted that the duration of our principal factor, the grasses, is practically perennial. Pollen disappears completely from the air only for a few weeks following a killing frost which does not occur until the second week in January, and reappears in the air in March, in small quantities it is true, but enough to annoy hypersensitive subjects. Ordinarily most of our grass seasons cases start in April. There is a slight subsidence of grass pollination in August, but a recrudescence in early September, coincident with the onset of the ragweed season. In fact, our grass pollination reaches its highest peak in September and October, and in this vicinity, pure grass autumnal hay fever and asthma are not uncommon, without additional ragweed sensitiveness.

The variety of pollen factors existing locally, the relatively large amount of pollen granules almost constantly in the air, the prolonged duration of the pollination season of our principal factor, the grasses, the selection of this point by chronic perennial asthmatics as a climatic resort, giving abundant clinical material, makes San Antonio an ideal spot for the study of the various phases of pollen sensitization in diagnosis and treatment. It is not only necessary for us to attain an immunizing dose sufficient to give clinical protection, but owing to the absence of the seasonal factor in almost all our cases, such protection must be maintained, a factor which does not enter into the consideration of these cases in the north and east.

With diagnostic presumption eliminated as a result of carefully made air pollens analyses eighteen months previously, checked up by actual field surveys, our efforts during the past year have been to secure a pollen extract dose in each instance that would afford absolute clinical protection. In many of our failures of past years the patients have been called back for purposes of study, and carried under experimental observation for many months. All cases were private, the patients being of rather more than ordinary intelligence. The pollen extracts used in this work were furnished by Dr. W. W. Duke of Kansas City (sixty-six and two thirds per cent. glycerine, thirty-three and one third per cent. Coca's solution). The total number of pollen allergic cases seen this year, 115, furnish the basis for this study.

Treatment, where possible, was preseasonal, of course, by at least three or four months. Owing to the fact that it was early realized that undoubtedly sensitiveness would differ in degree in these hypersensitive individuals, at the onset, an attempt was made to determine such variabilities in each instance by noting the dilution of the offending pollen extract failing to elicit a cutaneous reaction, and using such dilution as a basis for the inception of immunization treatment.

TECHNIC

The following preliminary routine testing dilutions were employed in each instance: 1:5,000, 1:500, 1:50, and 1:20 where previous weaker dilutions were negative. In most instances it was possible to secure a complete negative or only a very slightly positive skin reaction with the 1:5,000 dilution, permitting the inception of treatment with this dilution. Where the dilutions mentioned above all gave good undoubtedly positive reactions, tests were then repeated with dilutions of 1:20,000, 1:40,000, and on one or two occasions we were compelled to begin treatment with a 1:80,000 dilution, as in our experience no treatment is safe to start with that gives a positive skin reaction. However, on the other hand, this method of differentiating degrees of sensitiveness, often permits of the saving of a considerable amount of time by allowing treatment to be started with a 1:500 instead of the usually commercially recommended initial dose of 1:10,000. Doses

proceeded in the following sequence, a sequence which we have seen no reason to change: 0:05 c.c., 0:1 c.c., 0:2 c.c., 0:3 c.c., 0:4 c.c., except in changing from a 1:50 to a 1:20 extract, where the skip was made from 0.2 c.c. of 1:50 to 0.05 c.c. of the 1:20 extract. Succeeding doses of this strong extract were given as follows: 0.05 c.c., 0.1 c.c., 0.15 c.c., 0.2 c.c., 0.25 c.c., 0.3 c.c., 0.35 c.c., 0.4 c.c., 0.45 c.c., 0.5 c.c. Doses were given not twice a week but twice a day, and on several occasions three times a day, in the weaker dilutions, allowing an interval of at least three hours between doses. Cases were held under observation for at least a half hour following treatment, and the arms in each instance examined before any treatment injection was given, to determine the slightest evidence of cutaneous reactions resulting from the previous dose. When the 1:50 extract was reached, doses were then given daily instead of twice a day, and every other day with the 1:20 extract. The slightest erythema or induration at the site of the needle puncture called for a repetition of the dose as many times as necessary until its tolerance was denoted by the absence of the slightest evidences of cutaneous irritability (wheals, erythema, induration), and no treatment of any kind was given until all evidences of reaction induced by previous treatment had completely disappeared, no matter how many days were required.

COMMENT

The foregoing gives a rational method for the induction of tolerance, and in practice, works out well. What is being sought, is a definite tolerance sufficient to take care of an indefinite varying amount of air borne pollen, and to take care of any amount of such pollen for as long a period as it exists in the air. It has been our experience that the skin reaction, in all but a few instances, gives a reliable guide to dose and interval. If the skin is intolerant to a certain dose, there is no reason why the nasal or bronchial mucosa should tolerate it any better, and it has been our experience that if too large a dose is started off with, or if the increase in dose is persisted in, in a mechanical manner, disregarding the warnings given by the skin, hay fever, asthma, and at times intense urticaria and erythema multiforme will result, all symptoms of pollen anaphylaxis, which are free from serious danger. At times, in spite of all precautions, such reactions will be produced by the accidental deposit of treatment in a small vein. Epinephrin should be given at once in doses of from 0.5 c.c. to 1 c.c., and repeated every ten to twenty minutes until relief is secured. In fact, no one should do this work without having epinephrin at hand to meet this eventuality which may arise even from testing.

These severe reactions, and in fact even mild general constitutional reactions, aside from the risk and discomfort to the patient, are regrettable from another point of view, in that they increase hypersensitiveness. For instance, it is assumed that a patient has taken 0.1 c.c. of a 1:50 dilution without reaction. An intradermal test of this patient at this time will show a negative test to a previously 1:5,000 positive, and in most instances a negative or only a bare suspicious test to a 1:500 dilution, and only a bare + or ++ to a 1:50. Assume that with the 0.2 c.c. dose, a heavy reaction ensues. If this patient be retested for graduated sensitiveness next day, not only will the 1:50 extract dilution be found to give a ++++, but also the 1:500, and very often the 1:5,000, thus defeating the very end desired. We have found the continuance of the use of epinephrin two or three times a day for several days after the quiescence of the reaction a great help in reducing this hypersensitiveness, and treatment can then usually be safely resumed with a dose of about twenty-five per cent. of the one causing the general reaction. However, it had better be held at this point for one or two repetitions before increasing. We have found that in cases giving persistent local reaction with the daily use of any extract, it is frequently possible to secure the elimination of these reactions by increasing the dose interval to two or three days.

There is scarcely anything more discouraging, or more alarming, to the patient than a severe general reaction. What is being sought in these cases is the gradual induction of tolerance. Overdosing does not bring about but only delays this process. Pollen immunity is a tolerance rather than a real immunity, as bacterial immunity is apparently not prevented by the induction of rather severe general reactions, and is relatively permanent, as witnessed by typhoid prophylactic injections. The duration of pollen tolerance, on the whole, when once induced, usually is too fleeting to be a real immunity.

DOSES OF EXTRACTS REQUIRED FOR PROTECTION

The final dose of a pollen extract necessary for protection must vary according to the section of the country and the individual pollen, and can be learned only by hard actual experience. The dose of a grass extract in the north, with a three or four weeks' pollination season, must be vastly different from what is required in Houston or San Antonio, Texas, with a ten to twelve months' season and a vastly greater amount of pollen in the air. We cannot state anything positive about these necessary doses except for San Antonio cases. In our experience, this is as follows:

Spring grasses, 0.2 c.c. of a 1:20 dilution.
Fall grasses, 0.35 c.c. to 0.5 c.c. of 1:20.
Carelessweed, 0.1 c.c. of 1:20.
Ragweed, 0.2 c.c. of 1:20.
Mountain cedar, not fully worked out.

These are average figures. Several of our patients have attained perfect clinical protection on far smaller doses. In only a few of our grass cases has the final dose of 0.5 c.c. of the 1:20 extract had to be given. Ordinarily 0.4 c.c. was found sufficient. In not one of our cases have these doses once reached with the cessation of reactions, failed to give the desired clinical result. Unless such final dosages are reached without reactions, the patients are not immunized, and almost invariably continue to have symptoms.

It is regrettable that no method of standardization has as yet been discovered that will permit the comparison of the extracts secured from Dr. Duke with ordinary commercial extracts, but Dr. J. H. Black, of Dallas, Texas, has shown that our usual nitrogen determinations are of no value in this connection, (2), and no other method has been published.

Our efforts were to secure, not merely a dose that would afford a certain amount of protection, but a decided protection as shown by the elimination of the previously positive skin diagnostic test. As long as these initial skin diagnostic tests (ordinarily made with 1:50 extracts) remain positive at the end of treatment, any immunity secured by treatment is only partial at the best, and results will be uncertain. Relief can be counted on only in the presence of a short pollination season and interruptions of the seasonal pollen content of the air by intercurrent rainfall, or conscious or unconscious pollen precautions. Partial immunity secured by the advertised doses of the ordinary commercial extracts, in this end of the world of limited rainfall and prolonged pollination seasons, was not successful in over ten per cent. of our cases handled in previous years. As a matter of fact, in a number of our cases the hay fever or asthma has persisted unchanged following the complete elimination of these 1:50 commercial extract positive skin tests. These cases still showed positives to the Duke 1:50 extract, indicating its greater strength. Elimination of the positive skin test with the 1:50 Duke extract is a far more reliable guide to protection, but even this is not infallible.

NUMBER OF DOSES REQUIRED TO SECURE IMMUNIZATION

We do not consider this of any importance. It is absolutely impossible to make the slightest pretreatment estimate on this point. The number of doses will vary from forty to sixty, or even over a hundred in a stubborn case. We have had to repeat a single dose on occasions from five to nine or ten times to get by. In making this statement, consideration must be taken of the fact that most of our work is with seasonal cases having symptoms, and far more difficult to handle than the ordinary symptom free preseasonal case.

COMPARISON BETWEEN DAILY AND BIWEEKLY INJECTIONS

It is our opinion that the twice a day or daily method of giving treatment which we have used for the first time this year is far more satisfactory to all concerned. Out of town patients will readily consent to a few weeks of intensive treatment. Reactions to us seem fewer by this method, and tolerance far more rapidly secured, and relief to seasonal cases is infinitely more prompt.

DURATION OF POLLEN IMMUNITY OR TOLERANCE

Only a few patients, immunized in previous years and failing to report for treatment again this year, have remained well. While pollen immunity thus may be permanent, in most instances it is only transient, lasting at the best only a few weeks, and at times only a few days. We have had occasion to observe a number of patients whose treatment was carried to the point of elimination of the original 1:50 diagnostic test, who for one reason or another suspended treatment for three or four weeks. Retesting these cases has then shown + + + + positives to a 1:5,000 dilution and recurrence of symptoms and the work has had to be done all over again. It is our opinion, judging from analogy with our grass cases, that if the ragweed season in the north lasted three or four months, instead of six to eight weeks, most of the preseasonally immunized cases would relapse at the end of two months. But even here in San Antonio, this is not invariably the fact. One of our carelessweed cases, an extremely hypersensitive individual who gave a severe general constitutional reaction with his original diagnostic skin tests, and who was immunized in the spring of 1924 with great difficulty, had to give up treatment in the early summer. On retesting him in early July, his skin again gave a + + + + positive reaction to a 1:10,000 dilution, with constitutional symptoms from the tests. He was unable to resume treatment. Much to our surprise, he passed through the carelessweed season (July, August, September, October and early November) without the slightest signs of hay fever and without any change in previous environment or mode of living. Why, we cannot understand. Such cases in our experience are an extreme rarity, and for this reason, it is our custom not to permit the pollen immunity to lapse, once it has been induced. This is especially necessary in the grass cases, who make up the bulk of our work, on account of the ten to twelve months' pollination season. Polen immunity once induced can be maintained indefinitely by the use of the maximum dose first at biweekly and later at weekly intervals. The appearance of a cutaneous reaction during such immunity maintenance indicates a beginning loss of immunity and the necessity for the resumption of more frequent doses. We frequently accustom our patients to give this weekly maintenance dose to themselves.

DIAGNOSTIC TESTING METHODS

Our tests were all by the intradermal method, using approximately 0.01 c.c. of material. Many of our pollen cases were found in addition with positive skin tests to various animal hair emanations, foodstuffs, feathers, orris, etc. These factors were, of course, taken care of in the usual manner. When our patients showed the usual positive pollen skin tests, and in corroboration could be shown to be worse out doors, clearing up in closed rooms and relapsing with outdoor existence, they were considered pollen cases.

NASOPHARYNGEAL OPERATIVE PROCEDURES

In none of our cases of either hay fever or asthma were the patients given any local nose or throat treatment, though most of our chronic asthmatics had had various intranasal surgical operations done previously without benefit to such condition. In fact we never have the noses, mouths or throats of our allergic patients even examined, except occasionally for diagnostic purposes in the presence of definite urgent local symptoms indicative of pathology of no connection with the allergic symptoms. Our patients have secured full asthma or hay fever relief in the presence of chronic sinusitis, abundant polyp formation, dental, tonsillar or abdominal disease. We even had one patient lose his asthma under pollen precautions in the presence of a fatal carcinoma of the liver. We have found the usual aromatic oil sprays commonly used by otolaryngologists *definitely* harmful in these conditions, and limit our local treatment to a simple albolene spray in hay fever.

VACCINE THERAPY

No vaccines, stock or autogenous, were used at any me in the treatment of this series of cases. We ave not seen a single case of hay fever or asthma iat we could consider of bacterial etiology. We do ot include the bacterial proteins in our tests.

OCAL EXHAUSTION OF THE TISSUES TO FREQUENT INJECTIONS

In our experience, this is extremely doubtful. We ave on hand a motorman practically free from ymptoms for months, who is constantly in contact vith his pollen influence (grass) and whose precaucions can be only minimal, and consequently is an xtremely difficult case to immunize. He has reeived 0.1 c.c. of a 1:20 dilution in the same arm leven times, each time giving the same + or ++ ocal reaction until the twelfth injection, the local eaction reappearing unmodified on the thirteenth, ourteenth, fifteenth and sixteenth injections of the ome dose in the same area.

NDIVIDUAL SPECIFICITY OF CORRELATED BOTANICAL GROUPS

The question has been raised as to whether immunization with the short form of ragweed protects gainst the tall form, and vice versa. We used an xtract of the tall form exclusively for treatment this ear. While our treated cases were few in number three pure ragweed only, nineteen combined with rass), our clinical results have been practically perect in every instance. We have in San Antonio litle or no short ragweed. It is replaced by an abunlant growth of Gartneria tenuifolia of the same Compositæ family, against which giant ragweed reatment apparently gives perfect protection. Its ollination season lasts longer than the giant ragweed by two or three weeks.

The question has also arisen as to whether immunization against one grass protects against all. In this connection, we had a curious and interesting xperience. We started to immunize twenty grass ases in January, 1924, using commercial extracts of Bermuda and Johnson grass, our commonest grasses. By March the supply was exhausted, and no more ould be secured. In our dilemma, Sudan grass was suggested by Dr. Duke, and practically all of our subsequent work this year was done with extracts of this grass which grows here only in great scarcity, ut botanically is closely related to Johnson grass. When the supply of this material at times ran short, we found then we could do as well with timothy or lue grass, which do not grow here at all. The doses seem to us nearly identical for practically all working purposes.

We have also been greatly puzzled at the occurrence of another singular phenomenon which we ave not seen mentioned elsewhere and which has greatly disturbed our preconceived ideas of individual pollen specificity. A number of cases of double grass ragweed sensitiveness, in fact in the majority of such cases who started with ++++ positive skin reactions diagnostically, were tested at the conclusion of grass immunization treatment for both grass and ragweed, the ragweed being done in the usual manner to determine the degree of sensitiveness in order to institute additional specific ragweed treatment with appropriate doses. Much to our surprise, not only in these cases were the grass tests negative, but also the ragweed tests were either correspondingly totally negative, or reduced from a ++++ to a bare +. Treatment which we had expected to start with a 1:5,000 extract, we now found could be safely and easily started with a 1:50 or even a 1:20 extract. Several patients were not given ragweed immunization at all; others were given a few high doses as a precautionary measure. Certainly in this end of the world, a high grass immunity confers total or almost total immunity against ragweed. In the same way, we found carelessweed immunity in primarily carelessweed cases to give a high or total protection against both grass and ragweed.

Why large doses of grass or carelessweed extract afford complete or almost complete protection against a totally unrelated pollen, such as ragweed, we can only conjecture. Nevertheless, clinically, it is a fact. Our limited experience with primary ragweed cases does not give us any information as to whether in turn high ragweed immunization similarly affords protection against grasses.

HANDLING OF PATIENTS SENSITIVE TO MORE THAN ONE POLLEN

We do not use pollen mixtures. Since noting the high protection given by a complete immunization with the primary pollen against all other pollen factors, it has been our custom in all instances to carry our primary pollen immunization through to a conclusion, after which usually only a few doses of high dilutions of any other pollen factors are required. In many instances no other treatment beyond the initial immunization has been found necessary.

SEASONAL TREATMENT

Immunization is not practical in the presence of active hay fever or asthma. Unfortunately, most of our local cases of asthma and many of our hay fever cases are of grass etiology, and are seldom encountered in the two or three months of the year when they are comparatively free from symptoms. Sending patients away to the coast or to some desert section of the West is not always practical. While more difficult to handle in every way, these cases can, more often than otherwise, be cleared sufficiently for immunization purposes. Advantage can be taken of the fact that specific treatment can be administered at any time there is freedom from symptoms between attacks for three or four hours, the method of treatment, doses, etc., being identical with those of the preseasonally handled cases. Extreme care must be exercised to give no treatment in the presence of the slightest active symptoms. Inasmuch as such patients must perforce receive naturally an unmeasurable amount of air borne pollen at home or on their way to the office, the dose of pollen extract administered by the hypodermic needle does not represent the actual dose received. Also, it is impossible at times to state when a patient is one hundred per cent. clear of symptoms, and at other times it is impractical for a patient to remain a sufficient length of time in a closed up office to secure perfect clearing, and

chances have to be taken. Hence in these cases, reactions both cutaneous and general, are comparatively frequent, few patients escaping at least one or more mild constitutional reactions. Relapses are common, and the number of treatments necessary to attain the final protective dose far exceeds what is required in the preseasonally immunized case.

The following general measures will be found ordinarily successful in rendering a seasonal case symptom free. Existence, as far as possible, should be limited to the downtown sections of a good sized city away from contact with empty lot weed or grass growth, and indoors as far as possible, and in rooms on the opposite side of the house from the prevailing winds. In sleeping or working rooms, either no windows at all, or only a single window should be kept open, with all doors or transoms tightly closed, thus avoiding all air currents. An electric fan kept constantly in action day and night in front of the room's only open window prevents the entrance of much pollen, and makes the best pollen screen or filter we have been able to devise or secure. Automobile rides and trips out of the business sections of the city are, of course, forbidden.

In our cases of both hay fever and asthma we advise our patients, if not clear on arising, to take enough epinephrin hypodermically to become so, and to report for treatment within three hours. When patients reach the office not quite clear, we frequently have them wait in a closed room for a half hour or even longer, and then if not clearing sufficiently, administer epinephrin, and have specific treatment administered some two hours later. Patients living in the suburbs remain downtown from early morning until late at night. Such a routine reduces air pollen doses and suffices in all but extremely sensitive cases.

Naturally, it is impossible for all patients to maintain such an existence for any length of time. Instructions are constantly being violated, either through necessity or carelessness, producing a return of symptoms. As protection is gradually raised by interval treatment, larger amounts of air pollen are required to produce the attacks, which necessarily become less and less frequent, and less and less severe. However, such protection is only slowly and gradually induced, and intercurrent periods of high wind velocity increasing the usual pollen content of the air frequently (and usually) bring on a recurrence of symptoms, and repeatedly so, until full immunity has been established.

Also, it is frequently impossible to tell in these cases where epinephrin is being used, when symptoms are due to treatment overdosing or to the inhalation of air borne pollen, as epinephrin may at times mask or modify the guiding skin reaction. Also at times, accidental intravenous medication occurs. It is always safer to ascribe symptoms to overdosing, to resume epinephrin regularly with such relapses, and to wait for an interval of freedom from symptoms before taking up specific treatment again. Thus many disappointing delays naturally occur, and many partial immunizations, before an interval of freedom finally supervenes of sufficient duration to permit the attainment and several times repetition of the ultimate dose, and in our experience, especially with the old chronic perennial asthma cases we so often see here, full immunization is essential to secure relief. Naturally a certain percentage of patients become discouraged and discontinue treatment, or are forced to do so for one reason or other.

We worked on one case of grass hay fever one whole year before securing protection, and on a case of chronic grass asthma three years. Many, probably most of our cases, require from four to six months. In many of these cases, a dose is reached which seems impossible to pass on account of successive reactions, but persistency will usually finally get by. However, we do not doubt that there exists a certain very small percentage of patients whom it will be impossible to immunize at all, but usually from inability to remove them from pollen contact.

In two cases only were we unable to secure sufficient clearing up of symptoms to start immunization treatment where this routine was or could be employed, and it is doubtful if asthma exists anywhere any more severe or persistent than we see it here. By the routine mentioned, we have cleared up in a few days cases that have not been free for months, and also some old severe chronic cases where the patients' economic condition was such that it was absolutely impossible for them to avoid almost constant heavy pollen contact.

TABLE I

CLASSIFICATION OF CASES

	Hay Fever	*Asthma*	*Total*
Allergic cases of respiratory tract seen this year	54	121	175
Allergic pollen cases seen this year	47	68	113
Allergic cases, presumably grass, negative to grass tests	2	22	24

Preseasonal	2

	Grass	Ragweed	Mountain cedar	Grass Ragweed	Careless-weed Ragweed Mountain cedar	Total
Clear*	1	2	2	10	2	17
Improving	8			7		15
No improvement	3					3

*Improvement or clearing in these cases (except mountain cedar) considered due principally to pollen precautions and only partially to specific treatment; seventeen other patients started but did not complete treatment, only one attaining a high enough dose to be considered a possible failure. Two cases could not be cleared sufficiently for treatment, two cases undergoing clearing for treatment.

ALLIBILITY OF INTRADERMAL POLLEN SKIN TESTS. HYPODERMIC TESTS

So much has been said regarding the use of the kin tests in the diagnosis of pollen hay fever and sthma, that no detailed mention of the technic of heir employment is here required. The average ommercial diagnostic extracts are of 1:50 strength, nd used intradermally, on the whole, are very satisactory. But they are not infallible by any means, nd were diagnostic tests limited to their use, many case would be missed completely, especially of sthma, but also occasionally of hay fever. We ave had no experience with the ophthalmic tests.

Sensitiveness is a matter of degree and dose. The verage hay fever case will give a definite positive kin test to an extract of his offending pollen with dilution as low as 1:500 or 1:5,000, but not infreuently the sensitiveness is so slight that extracts f 1:50 strength will be negative and at times even f 1:20. Symptoms in these cases are due to the eception of enormous doses of pollen by the natural hannels. That this is not pure theory is shown by he fact that in some instances, treatment can be arried to the point of the complete eradication of the uge positive skin test originally secured with the rdinary commercial 1:50 diagnostic extract, without the slightest benefit to the asthma or hay fever, hich, however, will clear up if treatment is pushed o the use of the large sized recommended doses of 1:20 extract. Our experience with stronger xtracts for testing is too limited for any expression f their value.

We have been able to hold under observation eight f our patients with skin tests negative to all antiens, also seven patients previously considered pure eather or animal hair cases, either fully immunized gainst such factors or under strict precautionary nvironment, all of whom relapsed this fall (fall eing our heaviest pollination season), all with epeated negative pollen tests, thirteen with asthma nd two with hay fever. All gave histories consistent ith a pollen etiology. All these fifteen patients were ut under pollen precautions and treated empirically ith grass extract, on the ground that our most prevlent pollen might have something to do with their ases. Much to our surprise, all gave definite local eactions and occasionally constitutional symptoms t some time during routine grass treatment. Curiusly enough also, a few patients with negative or nsignificant grass tests have given definite ragweed ositive skin tests, but have their trouble also in the spring and summer, at which times our pollen plates show no Compositæ pollen granules. Ragweed immunization has not cleared up or improved these cases without additional grass treatment which has cleared them up.

In these presumably grass cases, five patients, in whom grass immunization has been completed, are free from symptoms. Six have improved to a degree consistent with the amount of grass extract received to date, though our grass season is still at its peak (November 20th), and four only have failed to show any improvement at all, as reactions are blocking all treatment progress.

Where the history of the patient gives the slightest indication of trouble in spring, summer or fall, irrespective of animal hair, food, feather or orris tests, we now test all such negative pollen cases hypodermatically with the following grass pollen extract dosages: 1:5,000, 0.05 c.c.; 1:500, 0.05 c.c.; 1:50, 0.05, 0.1, 0.2 c.c.; 1:20, 0.05, 0.1, 0.15, 0.2 c.c., often getting positives with as low as the 1:500 dilution. We consider no case negative to grass pollen unless the maximum dose mentioned can be reached without reactions. We now put all cases of this type under preliminary grass immunization and routine pollen precautions with very satisfactory results.

In other words, the pollen skin tests are not to be considered absolutely diagnostically dependable. Seasonal history probably justifies prevailing pollen immunization in other sections of the country, even in the absence of positive skin tests. Certainly our local experience justifies this statement. Dr. George Piness of Los Angeles (3), whose pollen problem is similar to ours, has had this same experience in testing with the grass extracts. The hypodermic tests we suggest and which we have not seen mentioned elsewhere, furnish a reliable diagnostic means of checking up these cases and avoiding the error of overlooking actual grass cases of this type. These hypodermic tests are given one each day, with a careful watch for delayed local or constitutional reactions. Our ragweed experience has been too limited to express an opinion as to whether some of its victims also fail to give positive skin reactions.

From the foregoing it can be readily seen that the diagnosis and treatment of pollen hay fever and asthma consist of a great deal more than the application of a few commercial diagnostic tests followed by a stereotyped sixteen or twenty dose course of treatment, not a single dose of which may be applicable to the case at hand. Partial immunity so produced may effect a partial success in forty per cent. or so of cases where there is a short pollination season. This is a far better figure than we were able to secure here for years before adopting the ideas and treatment methods brought forth in this article. This year with little rainfall and with the air seldom free for even part of a day from far heavier pollen content than we have noticed in any previous years, making atmospheric conditions as unfavorable as possible for our work, the actual results have been almost perfect.

Endocrines in Relation to Rheumatic Fever and Rheumatoid Arthritis

LLEWELLYN JONES LLEWELLYN, M.B. (Lond.)
London

(*Continued from page 621*)

CARDIAC DISORDERS AND THYROID INSTABILITY

So insidious are the beginnings of rheumatism in childhood, that none can tell the hour of its inception. Would it not be wise then to recognize betimes the diathesis? Is it not somewhat arbitrary of us to refuse to admit its presence until recurring tonsillitis, socalled growing pains or endocarditis give it, what we are pleased to term, an authentic stamp? The more so in that—despite the readiness with which children's temperature rises—their rheumatic manifestations are so often apyrexial. Thus both carditis and endocarditis are frequently from beginning to end afebrile,[1] and their refractoriness to salicylates is notorious. But even those wearisome cases in which endocarditis and joint swelling in a child drag on, defiant of salicylates, I have known clear up on the addition of cautious thyroid therapy.

That cardiac affections in children should run an afebrile course is very striking, but indeed, it appears to be a feature also of endocarditis in the rheumatic fever of older subjects. For as Sir Archibald Garrod long since pointed out, the incidence of endocarditis "has very little effect upon the curve." This is the more striking in that pericarditis causes a sharp rise. That endocarditis or carditis occasions little or no disturbance of the temperature would seem—as I have before suggested (2)—to predicate some local and specific difference in the pathological or biochemical reaction of these nonstriated muscular structures to the casual virus. Instinctively one recalls the controlling influence on the body temperature exerted by the thyroid and other endocrines. Thus, the temperature in myxedema or hypothyroidic subjects is commonly subnormal, but in Graves's disease and hyperthyroidism often a degree above normal. Now, seeing that children of rheumatic stock are often hypothyroidic, one can scarcely resist the inference that this thyroid deficiency is in some way responsible for the often apyrexial character of carditis and endocarditis in their instance.

Moreover, since the muscular and fibromuscular lesions in endocarditis are—as Ivy Mackenzie suggested—not incompatible with "a process of perverted metabolism of the muscle substance"—is it not conceivable that thyroid deficiency may occasion such perversion, with resulting myocardial degeneration. For, diminished thyroid secretion implies diminished tissue oxygenation, lessened katabolism, and inadequate elimination of waste products. Might not such metabolic obliquities be at the roo of the insidious apyrexial installation of carditis o endocarditis in a child?

Huchard has indeed suggested that congenita mitral stenosis may be the outcome of congenita thyroid deficiency, and we know, too, that in myx edema the cardiovascular system is severely involved The muscle fibres are infiltrated with fatty an mucuslike substances, while coincidently the vessel tend to undergo arteriosclerosis. Klippel has pointe out also that sometimes mitral stenosis coexists wit myxedema, and it is possible, too, that the retarde development of children with mitral stenosis ma hark back to a subthyroidic substrate.

RELAPSING ENDOCARDITIS AND AUTOSENSITIZATIO

The hypothyroidic substrate of the rheumatic chil with its correlated tendency to periodical phases o hyperthyroidism may be in part etiologically respon sible for recurrent or relapsing endocarditis. For, re calling the existence of organ specificity, I have else where suggested that in autosensitization we migh possibly find a clue to the source of relapsing endo carditis, viz., alternating phases of sensitization an desensitization.

Now, these reactive phases of hyperthyroidism ar presumably compensatory. But nevertheless, suc may determine attacks of migraine, asthma, derma toses, etc.—currently regarded as due to anaphylaxis Now, there seems no *a priori* reason why the cardia organ should be immune from the effects of suc periodic hypersecretion. Rather the reverse, seein that tachycardia is so cardinal a feature of hyper thyroidism. May it not be then that the cardia lesion is kept going by the periodical influx into th blood stream of an excessive and it may be also a pe verted thyroid secretion, viz., autosensitization or en dogenous anaphylaxis. As I have elsewhere re marked (4) the afebrile character of carditis an endocarditis in children is a feature more compatibl with an anaphylactic than an infective origin. Th relapsing nature of the endocarditis would on thi hypothesis be due to a series of mild anaphylacti poisonings.

But on this hypothesis, it would at first sight ap pear irrational to suggest thyroid therapy. Albei not if we recognize that the basal condition is one o hypothyroidism, or more correctly of thyroid insta bility. Hence our aim is to restore the endocrin balance—to inhibit the periodical phases of hyperth roidism and this by tentative thyroid therapy. Fo seeing that refractory joint swellings undergo rapi regression—if to salicylates be superadded thyroi therapy—then why should not the heart—a viscera joint—when the seat of carditis or endocarditi prove equally amenable, and my experience suggest that it is.

Albert Kocher, of Berne, wrote recently "hypo

[1]The controlling influence on the body temperature exerted by the thyroid and other endocrines, especially the adrenals, may possibly throw light on the marked differences obtaining between the rheumatism of childhood and that of older subjects. In nothing is the difference more marked than in this matter of temperature. The insidious chronic and often apyrexial character of rheumatism in childhood contrasts sharply with the acute fulminant pyrexial rheumatic fever of those past puberty with its further complication—fortunately rare—hyperpyrexia. In view of the regulating influence of the thyroid on the body temperature, is it not possible that thyroxin or some other hormone—capable of intravenous administration—may prove helpful in subduing the pyrexia.

hyroidism is not yet sufficiently known, very often evere rheumatism . . . and heart trouble of unknown origin are due to hypothyroidism and cured by transplantation of thyroid tissue. This is the nethod of choice in these cases as thyroid feeding often causes stomach trouble and is never carried on ong enough."

May I ask, is not the carditis of children also a "heart trouble of unknown origin"? How well nigh mpotent are we when confronted with relapsing carditis or endocarditis! Salicylates fail us and we fall back on rest and a pious hope in the *vis medicatrix naturæ!* Knowing full well that even if recovery takes place it but too often leaves as a legacy immutable if not progressive organic lesions. Surely cautious thyroid therapy may well be given a trial. A trial—tentative as it always should be—but if it occasion palpitations or precordial pain it is not necessarily a signal for discontinuance. For, as Hertoghe has shown, such disquieting symptoms may ensue in a subthyroidic subject on thyroid therapy owing to rapid dissipation of infiltrating substances from the cardiac muscle. So rapid is their disappearance that the heart requires time to readjust itself to the altered musculature, this it does if the recumbent position is maintained and the thyroid dosage be appropriate, and in this matter every patient is a law unto himself. Kocher, as we see in "heart trouble of unknown origin," favors the somewhat heroic expedient of a thyroid graft. It may be that we yet come to this—a small price to pay if we could control or happily arrest the too often progressive cardiac lesion with its Nemesis—organic heart disease!

THE RELATIONSHIP OF THYROID DISORDERS TO RHEUMATIC FEVER

As West long since observed, a previous history of rheumatic fever crops up with suspicious frequency in the victims of Graves's disease. It was so in a series of cases of exophthalmic goitre that I recorded in 1904, viz., rheumatic fever, tonsillitis and sore throats figured largely as antecedents. More recent observations, too, by McCarrison and others clearly indicate that rheumatic fever in some way predisposes to the development of Graves's syndrome which may indeed evolve directly out of a thyroiditis installed during the course of the former malady. Again, tenderness of the thyroid or a subacute thyroiditis has been observed also in chorea and unquestionably the latter disorder has affinities with Graves's syndrome. One may note, too, despite its disputed etiology, that acute thyroiditis has been observed in a child suffering from erythema nodosum.

But interest centres chiefly upon the frequency with which thyroiditis—acute or more often subacute—arises in rheumatic fever. Originally remarked by—I believe—Vincent of Val de Grace our French confrères attach diagnostic importance to tenderness of the gland in this connection. Often, however, the thyroid swelling passes unnoticed as the victim—naturally preoccupied with his arthritic pains—rarely calls attention to the "tenderness" of his neck—an indication for routine palpation of this region, in rheumatic fever. Often, too, the thyroid implication is wholly masked so that its occurrence is only retrospectively diagnosed in light of the symptoms of hypothyroidism which supervene later and this far more commonly than is generally realized. On the other hand, the thyroid may be profoundly disorganized as in a case recorded by Marfan in which a state of myxedema evolved directly out of an attack of "acute rheumatic fever with angina."

It may be postulated then, that rheumatic fever induces a predisposition to Graves's disease or on the contrary and more often determines or is followed by a state of hypothyroidism. Now, most authorities agree that rheumatic fever is distinctly hereditary and not seldom attacks several members of the same family. What then is the nature of the morbid potentiality transmitted, and what also is the medium whereby its hereditary transference is secured? The answer to this etiological riddle—I submit—resides in this association of rheumatic fever with Graves's syndrome on the one hand, and hypothyroidism on the other.

Now, hereditary susceptibility with a tendency to familial distribution is characteristic of Graves's disease. In states of hypothyroidism also, hereditary transmission is the rule. Hypothyroidic women bear hypothyroidic children. In short, thyroid instability is transmissible—glandular heredity.

The phenomena of rheumatic fever and thyroid instability being so intimately interwoven, I would proffer this suggestion, that the hereditary transmission of these endocrine defects and chronic joint disorders may yet prove the basis of the arthritic diathesis so beloved of our forefathers—and the means whereby its hereditary transference is ensured.

RHEUMATIC FEVER AND THYROID INSTABILITY

All the foregoing data seem indicative of some interrelationship between rheumatic fever and thyroid instability. I use the term instability advisedly. For does not the very frequency (sixty-eight per cent. Vincent) with which reactive swelling of the thyroid occurs in rheumatic fever seem to postulate some latent thyroid inadequacy. Freund noted that such reactive swelling of the thyroid in pregnancy is much more common (ninety per cent.) in women residing in goitrous regions. In other words, the strain of pregnancy unmasked the latent thyroid insufficiency. In like fashion, may it not be that an attack of rheumatic fever makes manifest a latent or preexisting thyroid defect, i. e., hypothyroidism?

Doubtless the thyroid reaction in rheumatic fever is defensive for, be it noted, if the glandular swelling be fleeting or absent the disease displays a vicious tendency to chronicity. Have we not here a tacit indication that the determinants of rheumatic fever—microbic or other—favor a hypothyroidic soil, as the less marked the defensive thyroid reaction the more virulent and unrestrained appear to be the morbid effects.

RHEUMATIC FEVER AND HYPERTHYROIDISM

While it would appear probable that rheumatic fever develops by preference on a subthyroidic substrate it seems legitimate to assume that the reactive swelling of the thyroid is compensatory—an effort to restore endocrine equilibrium. For viewing the clinical syndrome of rheumatic fever, how reminiscent its general symptoms are of hyperthyroidism!

Thus, in both conditions we get quickened pulse, profuse sweats, fever, hyperglycemia, and diminished

calcium content of the blood. True, as Vines observes, these same symptoms may also be the expression of sympathetic excitation in response to infection. Nevertheless, how well nigh impossible it is to differentiate sharply the symptoms of hyperthyroidism from those of sympathetic excitation! Seeing how intimately interwoven are the thyroid and adrenal sympathetic system—the thyroid stimulating and in turn being stimulated by the adrenals.

But even if we take the more restricted view upheld, e. g., by McCarrison, viz., that the symptoms of pure hyperthyroidism are "loss of weight, gastroenteritis, diarrhea, and an increase in pulse rate proportionate to the increase in metabolism," the supposition that hyperthyroidism plays a part in the symptomatology of rheumatic fever is still tenable.

For certainly quickened pulse and rapid wasting are present while gastroenteric derangements are salient features both in the rheumatism of childhood and rheumatic fever. Thus, Poynton on this point states "children of rheumatic parentage are liable to attacks of bilious vomiting, with white constipated stools, and at the commencement of an acute attack vomiting and diarrhea, with much mucus in the stools may occur, while in adults, severe gastric pain with vomiting and diarrhea, or attacks of pain along the colon, may add greatly to the severity of the disease."

The presence then of symptoms suggestive of hyperthyroidism seems fairly assured, and there is, I think, evidence also of associated sympathetic excitation. To begin with, we have hyperglycemia and diminished calcium content of the blood—features common to both rheumatic fever and Graves's syndrome. In light of this, visualize for a moment the clinical picture presented by rheumatic fever plus a swollen thyroid. The quick pulse is there, the profuse sweats and wasting, as well as the enlarged thyroid, and if to these were but superadded proptosis and tremor, we should straightway be confronted with the coexistence of rheumatic fever and Graves's syndrome. An assumption not so improbable when we realize that Graves's disease has been known to evolve directly out of a thyroiditis installed during rheumatic fever. This overlapping of the two syndromes seems to confirm my supposition that the heightened excitability of the sympathetic system—so distinctly a feature of Graves's syndrome—also obtains in rheumatic fever. This the more likely in that it is well recognized that Graves's complex frequently—after a variable interval—follows in the wake of rheumatic fever. Or, failing this, that symptoms of hyperthyroidism—quickened pulse, wasting, and gastroenteric disturbances, e. g., colitis, dilatation of stomach—may persist after the close of rheumatic fever—as judged by the regression of articular symptoms and may indeed be the interconnecting link between relapses of the disorder.

Meanwhile, however, we must not lose sight of the fact that while Graves's syndrome, or a condition of hyperthyroidism may follow rheumatic fever, a much more common sequel is a state of hypothyroidism. Nevertheless, this, too, does but strengthen the supposition of endocrine—sympathetic implication as an integral part of the syndrome rheumatic fever. For given that a state of hyperthyroidism obtains during rheumatic fever, it may readily happen that—through functional exhaustion of the gland—a condition of hypothyroidism may subsequently ensue.

To sum up, thyroid instability in rheumatic fever apparently involves three phases. Preexisting latent or avowed hypothyroidism giving place during the disorder to a phase of reactive hyperthyroidism with as a sequel either Graves's disease, continued hyperthyroidism, or more often hypothyroidism.

THE ARTICULAR LESIONS OF RHEUMATIC FEVER

The question now naturally obtrudes—what of the joint swellings? How do they accord with these views, and here I would revert to the differences—*qua* joint involvement—between the rheumatism of childhood and the rheumatic fever of later life.

In the former, joint swellings are relatively rare, and even when present usually amount to nothing more than a light puffiness of wrist, ankle, or knees which recalls Goodhart's observation that rheumatic children were prone to tetany. Now, this disorder is sometimes complicated by periarticular swellings whence the term rheumatic tetany. This appellation, however, is now looked at askance and the joint swellings not classed as rheumatic, but referred to "vasomotor and trophic disturbances of innervation."

Now seeing that articular rheumatism in childhood usually connotes simply edema over one or two joints, is there any *a priori* reason why these should not likewise be of vasomotor and trophic origin? I know of none, and turning to the widespread joint swellings of rheumatic fever similar doubts intrude. Does not the fleeting nomadic nature of the lesions—the very completeness despite repeated swelling and retrocession—of their *restitutio ad integrum*—seem to indicate that some special mode of pathogeny is responsible for these vagaries—so alien to streptococcal and other infective arthritides.

Salicylates, too, in the latter are impotent, and as Ivy Mackenzie observes there is "no instance of infection outside the protozoal group yielding to a drug of this kind." Do not these peculiarities instill a doubt as to whether the joint swellings are not arthopathies rather than arthrites? That if of infective origin, they are not directly so—but indirectly—the intermediary mechanism being some instability of the vasomotor centres affiliated to the neuroendocrine system induced secondarily to infections or other agencies.

Does not the symmetry also of the articular lesions—at least in the serial sense—seem to predicate the intervening of some central controlling influence? Does not also the invasion and reinvasion of individual joints savor something of the paroxysmal or periodical—something reminiscent to my mind, of that curious disorder, intermittent hydrarthrosis? This latter seems linked up with thyroid insufficiency. It has been met with in goitre—it almost always disappears during pregnancy which is suggestive of autothyroid therapy—a supposition the more plausible in that similar results have followed in the nonpregnant after thyroid treatment.

Now, as I have remarked, rheumatic fever—when rebellious to salicylates—relents if thyroid be superadded. Moreover, it is somewhat remarkable that though rheumatic subjects—as evidenced by cardiac disorders—often become pregnant yet—(if we ex-

cept chorea gravidarum) I have—despite wide search in standard works—failed to find one recorded instance of rheumatic fever occurring during pregnancy. Has the thyroid hypersecretion during pregnancy anything to do with this immunity? For the immunity ceases with the delivery as, according to some, rheumatic fever not infrequently arises in sequence to prolonged lactation.

This apparent immunity from rheumatic fever during pregnancy—in itself arresting—is enhanced in interest in that a like freedom is enjoyed often (while pregnant) by the victims of migraine, asthma, Raynaud's disease and angioneurotic edema. For all these disorders are apparently the outcome of vasomotor and secretory disturbances of neuroendocrine origin. The which is interesting in light of my suggestion that the joint swellings of rheumatic fever may be of similar genesis.

But if of vasosecretory origin, how is it determined? Now, Hertoghe and others have noted that excessive thyroid therapy sometimes determines fleeting articular swellings and pains. Indeed Levi and Rothschild hold that the joint lesions thus produced may be difficult to differentiate clinically from those of rheumatic fever. But is it not true also that the joint swellings in rheumatic fever—though rebellious to salicylates—are dissipated by combined salicylates and thyroid therapy?

These findings at first sight seem paradoxical. But not so if in rheumatic fever we have regard to the correlated thyroid in stability, viz., a basal hypothyroidism associated with reactive phases of hyperthyroidism. For under such conditions of imbalance tentative thyroid therapy—by restoring endocrine equilibrium—may inhibit the tendency to paroxysmal thyroid hypersecretion. Indeed, the swift rise and wane of the joint swellings—their flitting from place to place—seem to predicate synchronous variations in the causes operative. Hence my suggestion that they may be due to phases of hyperthyroidism with its correlated sympathetic excitation, and these again in turn due to concomitant fluctuation or intermittency on the part of those agencies—microbic or other—that tend to inhibit the functional activity of the thyroid.

That endocrines other than the thyroid are concerned is certain, for with the advent of puberty, genital hormones come into play, and the intimacy of their functional correlation with the thyroid and of both with the adrenals need not be labored. Moreover, we know the reversible interactions of the thyroid and adrenals and their close relationship with the sympathetic system, of which the latter are indeed an integral part.

Seeing therefore how important a rôle the efferent sympathetic fibres to a limb play in regulating the blood supply to the skin and deeper structures as well as the cutaneous secretion, is it not conceivable that instability in the exercise of this function might occasion local circulatory and secretory disturbances in the joint structures. Not so improbable when we realize that one of the most striking peculiarities of the subthyroidic rheumatic child is their state of vasomotor ataxia or instability—with its correlated liability to dead fingers or even actual Raynaud's syndrome—which latter again, may, like tetany, be complicated by fleeting joint swellings or effusions.

One may indeed well ask, what is the inward significance of this overlapping of tetany, Raynaud's syndrome, rheumatic fever and Graves's disease? Tetany and Raynaud's disease we realize are linked up with subthyroidism or thyroparathyroid defect, but why, when we touch on the endocrine affinities of rheumatic fever, content ourselves with the bald statement that it apparently predisposes its victim to Graves's disease.

For, does not the very fact that Graves's syndrome may arise forthwith out of rheumatic fever clearly postulate that the innate morbid potentialities that make for the former are inherent in the victim of the antecedent rheumatic fever. In short, that rheumatic fever does not so much predispose to Graves's disease as that both these syndromes, like tetany and Raynaud's complex, hark back to a common etiologic substrate—subthyroidism, of which they are presumably but clinical variants.

Indeed, judging by its affinities for endocrine disorders it does not seem inconceivable that rheumatic fever itself also may be a neuroendocrine syndrome evoked by infections, possibly in the tonsils, but more probably in the gastrointestinal tract. Possibly, as has been suggested in regard to Graves's syndrome (McCarrison) to toxic products released through the action of anaerobic bacteria on proteins or amino acids, which through their action on the thyroid and adrenal sympathetic evoke Graves's syndrome. Seeing then that Graves's syndrome may in some cases be apparently but an extension, as it were, of rheumatic fever, why should not the same factors be at work in the latter disorder? For this much at any rate is certain, that enucleation of the tonsils confers no immunity from rheumatic fever nor freedom from recurrence of the same when previously suffered from.

GASTROINTESTINAL INFECTIONS

The gastroenteric crises, vomiting, diarrhea, that sometimes mark the onset and so commonly punctuate the course of Graves's syndrome, are somewhat strikingly paralleled in the rheumatism of childhood and in rheumatic fever.

In children, vomiting and diarrhea with much mucus may usher in acute rheumatism, while their tendency to periodical vomiting and mucous colitis is well recognized. Again, vomiting and diarrhea with severe pain are common in rheumatic fever, the diarrhea may alternate with constipation and as in Graves's syndrome mucous colitis and dilatation of the stomach are not uncommon.

Now, we know that thyroxin is a derivative of the amino acid tryptophane, the disruption of the latter being achieved by the putrefactive or indole producing bacteria. Normally only a certain percentage of tryptophane passes to the thyroid, the remainder being decomposed in the intestine by the indole producers and passing out in the urine in the form of indican and organic sulphates.

Now, D. J. Harries's researches show that the absence of indican from the urine indicates the absence of indole producers from the intestine. Under these conditions the whole, and not the usual moiety of the tryptophane is absorbed and available for thyroxin formation. Harries finds that with the disappearance of indican and organic sulphates from the urine, the familiar syndrome of hyperthyroidism ap-

pears. Accordingly, he deems Graves's syndrome due to excessive absorption of tryptophane following the disappearance of indole producers from the intestine, and he holds therefore that the early disappearance of indican from the urine in exophthalmic goitre is of serious prognostic import.

Now, seeing that Graves's disease may arise directly out of rheumatic fever it would seem desirable that this latter disorder also, should be investigated from this point of view, viz., the absence or not of indican in the urine. I proffer this suggestion inasmuch as I can find no reference—neither in standard textbooks nor special monographs on rheumatic fever—to the presence or absence of indican in the urine. Should research on this point establish absence of indican, it might explain why a too early resort to meat broths so often occasions a relapse in rheumatic fever. For in Graves's disease Harries finds that in the complete absence of indican and therefore of putrefactive organisms, administration of meat aggravates the symptoms. Lastly, the gastrointestinal derangements in rheumatic fever call for bacteriological investigation in view of their possible etiological relationship to the disorder.

RHEUMATOID ARTHRITIS AND ENDOCRINE DISORDERS

Vincent Coates and Gordon—discussing the etiology of rheumatoid arthritis—remarked that "A history of rheumatic fever seems to occur more frequently than can be accounted for by the incidence of this disease in the general population." With this I thoroughly agree, and seeing the intimate association of rheumatic fever with Graves's disease and still more with hypothyroidism, is it not highly significant that in rheumatoid arthritis also we find again this same intimate relationship, viz., with Graves's syndrome and hypothyroidism. In 1904 I recorded fourteen examples of the complete and six of the larval or incomplete type of Graves's syndrome coexisting with rheumatoid arthritis. A previous history of rheumatic fever, rheumatism, tonsillitis, sore throats was elicited in no less than twelve cases. Fourteen suffered also from Raynaud's disease in their extremities, in two the Graves's syndrome antedated the rheumatoid arthritis. In the majority the two arose concurrently, but in one or two Graves's disease was engrafted upon a preexisting rheumatoid arthritis. In one instance in which Graves's syndrome preexisted recession of the thyroid swelling was quickly followed by the installation of rheumatoid arthritis. Hence my suggestion that in cases of rheumatoid arthritis "with apparently atrophied thyroids and possibly in others some benefit might accrue from thyroid administration." In addition I have recorded examples of the coexistence of Graves's disease, rheumatoid arthritis and partial or complete myxedema, while the coexistence of rheumatoid arthritis with minor signs of hypothyroidism, sometimes with goitre, is not uncommon.

INTERCONNECTING SYNDROMES

In the case alluded to above it is significant that during the period intervening between the thyroid recession and the subsequent rheumatoid arthritis, the patient developed Raynaud's disease—this forming, so to speak, an interconnecting syndrome, and in my work on *Arthritis Deformans* I emphasized the extreme frequency with which such vasomotor phenomena preceded rheumatoid arthritis (5). The Raynaud symptoms often develop quite suddenly after some infective or toxic disorder—rheumatic fever, tonsillitis, influenza, gastrointestinal derangements, etc.—to be complicated in a few weeks or months by joint swellings. In some examples originating in alimentary disorders or after pregnancy or prolonged lactation, the interconnecting syndrome was that of tetany (6). The latter is clearly an indication of thyroparathyroid deficiency, and, as I believe, the Raynaud's syndrome also, viz., as previously suggested, they hark back to a common subthyroidic substrate. The paroxysmal incidence of the Raynaud phenomena may be due to reactive phases of hyperthyroidism, or possibly—so intimate is the thyroadrenal association—to phases of hyperadrenalinemia. I can vouch for the efficacy of thyroid therapy in Raynaud's syndrome, but good results have also followed adrenal treatment. Again, both thyroid and parathyroid have been found useful in tetany, and rheumatoid arthritis. Other interconnecting syndromes to be mentioned are migraine and asthma. The former often disappears with the onset of rheumatoid arthritis. Asthma often, too, but I have seen the bouts of asthma alternate strikingly with remissions and exacerbations of the joint swellings in early rheumatoid arthritis.

(*To be concluded*)

Milk Parenterally in Arthritis

JOSEPH EIDELSBERG, M.D.
New York

Since Schmidt and Saxl (1), in 1916, pointed out the protein reaction following the intramuscular injection of milk, many workers in all parts of the globe have applied this means of therapy to various diseased states. Bessau (2) and Mueller (3) affirmed that the reactions were due to bacterial content, but Uddgren (4) in 1918, working with sterile milk, found similar but milder reactions. More recently, hundreds of observers have studied the reaction and the effects, and though not universally obtained, nearly all agree that certain desirable effects are produced. The application to arthritis itself, and the partial understanding of nonspecific protein therapy and the protein reaction followed. R. Müller (5) in 1918, A. Weiss (6) in 1919, Schulman (7) in 1920, Eidelsberg (8) in 1922, among others, pointed out more or less frequent improvement in arthritis, acute, subacute, and chronic. During this time, it became conclusive, that salicylates failed in many cases, that diet restriction and diminished car-

bohydrate intake helped many, that proteins of various kinds parenterally helped others, that removal of apparent foci of infection frequently aided or cured, but just as frequently failed dismally, and so on. This brought up the question, why do we obtain

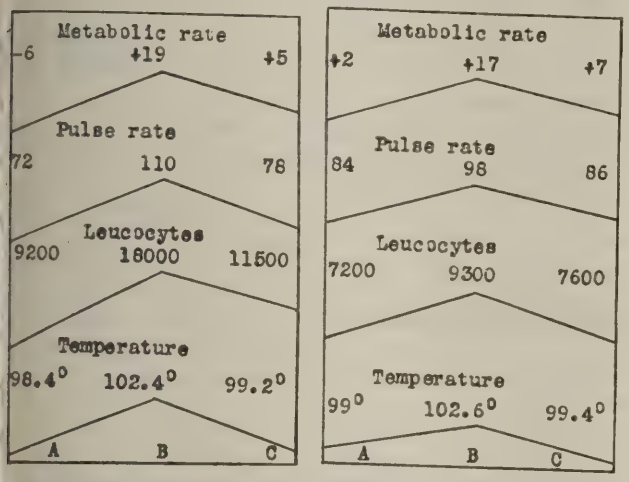

FIG. 1.—Examples of changes in temperature, leucocytes, pulse rate, and especially metabolic rate. (Cases G. L. and R. T.) A, at injection; B, after eight hours; C, after twenty-four hours.

the same effect with such widely different methods of therapy? Why does injection of milk in one case, and administration of thyroid in another, give decrease in pain and increase in function? Why, following any operation or a fatiguing journey, or an intercurrent infection, does a remission occur?

I can but refer to several of the numerous explanations and theories, summarized by Peterson (9), e. g., Weichardt's theory, selective stimulation, Wolf's theory, and many others.

As to removal of foci of infection, an evident state of affairs presents itself. The patient enters the scene with numerous joints swollen and distorted. The tonsils or teeth, the appendix or gallbladder, or what not, are studied and found infected. These foci are removed, and the condition remains the same. Each joint, and in one case as many as twenty, thirty or more separate joints are involved, each a secondary focus of infection, and each left remaining, to reinfect new joints, and form still more foci. Obviously then, we are unable to do more than scratch the surface of the sites of infection, and the patient progresses, only too often, from bad to worse. By this time the damage is so severe, the atrophy is marked, ankylosis, new bone formation, and the invalidism is so severe, that cure is out of the question. Then metabolic changes have appeared, as well as decreased sugar tolerance, decreased metabolic rate and other changes. Consequently, though the removal of foci of infection will and must be practised, we must search further to better our therapeutic armamentarium.

In 1921 I showed (10) that often, following injections of milk intramuscularly, there was a reduction in blood sugar level, which to begin with frequently was somewhat above the normal. Pemberton (11) had already pointed out that many cases of arthritis were associated with a definitely decreased sugar tolerance, and also showed how removal of a focus of infection, if followed by improvement or cure, was associated with an increase in sugar tolerance, the curve approaching the normal.

We then turned our attention to the study of the relation of what Pemberton showed, and our observation of the decrease in blood sugar level in many cases of arthritis, following the injection of milk. In cases showing improvement, if a decreased sugar tolerance existed, an increase in tolerance often went hand in hand with the improvement. Incidentally, the lack of uniformity in results, and the often peculiar curves, must be accounted for in part, at least, by the hurried or delayed sugar absorption in some cases, and the presence of metabolic or endocrine diseases in others, which would of course upset the curves. (Fig. 2.)

In the light of this, we can have a rational explanation of the low carbohydrate intake and our restricted diet, and among other things, of how milk parenterally aids arthritis.

Then, why the frequent observation of improvement following an intercurrent infection, as fever, a long journey, any excitement, administration of potassium iodide or thyroid substance, and now thyroxin? Pemberton suggests (11) that these measures, among others, hasten the body metabolism. What is the effect on the metabolic rate of milk administration parenterally? As it was expected, the injections frequently gave a fever, more or less severe, often absent, an increase in pulse rate, also often absent, and frequently an increase in the metabolic rate. The cases showing the combination of fever, leucocytosis, increased pulse rate, and an increase in the metabolic rate invariably gave the best results. (Fig. 1.)

These are only several of the ways and means of the action of proteins and other substances producing socalled protein shock, but they help to explain the enigma, and remove some of the empiricism hitherto associated with this form of treatment.

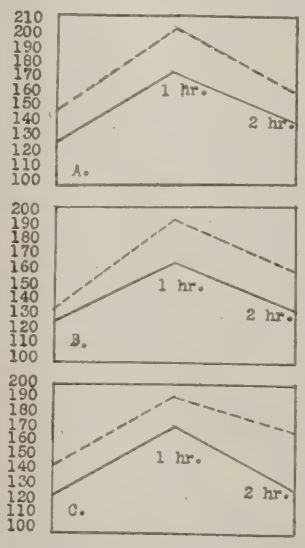

FIG. 2.—Examples of changes in sugar curves. A, Case G. A., received fourteen injections. B, Case R. T., received twelve injections. C, Case P. V., received six injections. Dotted line, before treatment; unbroken line, after six to fourteen injections.

We have given in all since 1920 several thousand (two thousand six hundred) injections, in about two hundred and fifty cases. One is too often disappointed by the results, but then how often do all our methods of procedure and therapy fail us. Even progression is sometimes not halted. Five cases have definitely regressed from what one would term an advanced state, fourteen patients, mostly early cases (five to ten months' duration) have been cured—107 patients improved in varying degrees—a number have ceased progression, even though not improved—and many, many failures. Too often the pathology is extensive, the disease extremely malignant

and progressive in nature—frequently associated with endocrine and metabolic disturbances, ankylosis, atrophy, exostoses, and what not—and cure out of the question. The underlying pathology remains —really unaffected. Any improvement, any aid is welcome. Cures are not to be thought of, and should never be promised. Then, and then only, is any improvement welcome and any aid a blessing.

CONCLUSIONS

1. An explanation of why removal of foci of infections fails to aid many cases of arthritis is discussed.

2. An explanation of why all forms of treatment fail in many cases is suggested due to secondary metabolic and endocrine changes, and too extensive pathological changes.

3. Observations have shown a decided increase in sugar tolerance in arthritis following milk injections.

4. Following milk parenterally there is an increase metabolic rate in many cases, associated with the improvement.

Aftereffects of Tonsil Operations

THOMAS M. STEWART, M.D.

Cincinnati, Ohio

The mistaken idea prevails that removal of tonsils is followed by a cure, or at least by great relief, of a large number of diseases. It is also the mistaken belief of most physicians that total removal of the tonsil by a cutting operation is the only thing to do.

The late Dr. Makuen, one of the best throat specialists, in the NEW YORK MEDICAL JOURNAL of March 11, 1916, says: "Some of my best results in tonsil cases have been obtained by merely opening several crypts. This and enlarging their openings will remove serious and constant sources of infection." Dr. Makuen wrote the foregoing before we had perfected the use of the high frequency technic in reducing in size large tonsils, and sterilizing tonsil tissue so that abnormal conditions were done away with. Therefore the tonsil operation with the knife is not the only way to get rid of tonsil infection .

Dr. Makuen also said in the same article that: "A tonsillitis is not a local disease. It is a local expression of a systemic condition. To remove tonsils for a recurring tonsillitis, would be like removing the entire walls of the throat to guard against a recurring pharyngitis."

The question has been asked: "Does rheumatism return after tonsils have been removed?" The answer is yes. The reason for this can be proved from Guy's Hospital Report, 1923. Thirty-five recurrences of acute rheumatism were reported following sixty-six operations on children's tonsils. And there were only thirty-three recurrences in seventy-eight cases in children on whom no operation was done.

May this be an exceptional record of recurrent rheumatism after removal of tonsils? The record is not exceptional for another series of ninety-six cases of which fifty cases had their tonsils removed, and rheumatism returned in twenty-three of them. And no operation was done in the remaining forty-six cases and recurrence occurred in but fifteen of them.

It may be asked: "Of what benefit is the tonsil operation in second attacks of rheumatism?" The answer is: "Of none whatever." Why? Because in another series of forty-eight cases reported by Guy's Hospital, sixteen of them had their tonsils removed and recurrences were noted in twelve. No operation was done on the other thirty-two, and recurrences occurred in only eighteen.

This shows that the tonsil is of some value to the human body. Recurrent attacks of the very things for which removal of the tonsils is strongly advised do occur. And these recurrences are more frequent in patients from whom the tonsils have been removed than in the cases where the tonsils remain.

It might be well to correct another wrong conclusion and that is the effect of the tonsil on the heart.

Dr. Davis (1), of Roanoke, Va., says that, "In seven thousand five hundred cases of diseased tonsils and adenoids in school children, heart disease occurred in but a small number; and that gland glands occurred just as often after as before the tonsils were removed."

Dr. St. Lawrence (2) states that: "A second tonsil operation was required in twenty-two per cent. of my cases referred to throat specialists for operation."

It has been shown after an analysis of many hundreds of cases that removal of the tonsils cures only about half of the cases of mouth breathing, quinsy and sore throat.

In many thousand cases studied by Dr. Kaiser, of Rochester, N. Y., it has been shown that removal of the tonsil does not prevent diphtheria.

Dr. Clendenning, of Kansas City, Mo., says, "lung abscess frequently follows removal of the tonsils. It is sometimes fatal, always serious, and often very crippling."

The Chief Medical Examiner (3) of the Philadelphia schools warns against the snap judgment of school nurses. He says: "Each individual case must be judged solely on the condition present in that case."

The tonsil operation is not a trivial operation because alarming hemorrhage is frequent, and deaths are not reported as in any way due to tonsil operations from my own investigation of returns from seventy-one cities in the United States.

To prove further the seriousness of tonsil operations, Dr. Sheedy (4) says: "Of one hundred cases examined months after operation, more than eight per cent. of the patients had deformed throats. C

these eighty patients, thirty-four complained of speech defects for from one to three weeks after operation; sixteen for more than three months; while four had lost permanently their singing voice. Only twenty-five per cent. of the patients stated that their throats felt better, and that they could speak and sing better after operation than before. Inability to use certain words had continued with five per cent. of the patients for more than six months after operation."

The causes for the ache in joints, sore throat, cough and other troubles either after a tonsil operation or in cases in which the tonsils still remain, are very often due to faults in diet. Errors in diet are a frequent cause of disease.

Frequently it has come to my attention, after patients have been overpersuaded "to have tonsils removed," that the same general trouble persisted. The teeth would be removed and in desperation, the patients have returned to me for advice.

Investigation revealed, for example, that one patient had followed our explanation as to variety in diet and the drinking of more water, but fruit was eaten daily. Now fruit taken daily, even in variety from day to day, is not tolerated by some people. Stopping fruit daily, that is skipping a day, removed the trouble in the joints.

Another patient had had our treatment but he was persuaded "to have the tonsils out, as the only sure way to get rid of the infection." He was operated upon. No improvement followed. Then the teeth were removed and no improvement followed. In addition to the joint pains he had a pain in the region of the gallbladder, a constant ache.

A gallbladder operation was advised; but before it was done the patient returned for our advice. Inquiry revealed the fact that he ate oranges one day and grape fruit the next day, thinking that this was variety so far as fruit was concerned. In other particulars he was all right, except that he ate a boiled egg every morning.

We advised and explained again variety in diet, and warned against an egg daily. The result was "uncanny" to quote the patient. In other words his trouble was dietetic, and he had had a tonsil operation and dentist work that he did not need.

In the words of Dr. Curran: "No one is justified in taking a greater risk when a lesser one may be successful, especially if it will not add to the danger of relieving the trouble with the greater risk later in case of failure."

Therefore our point is, why not first treat the tonsil by the aid of high frequency currents and the x ray? Then if the necessity arises, operation may be done.

In either case false hopes as to the aftereffects must not be encouraged.

Indicanemia

GUSTAV BAAR, M.D.
Vienna, Austria

This report is based upon ninety-eight cases examined at the clinic of Professor Wenckebach, at the Allgemeine Krankenhaus, Vienna. One hundred and twenty-six analyses were made for residual nitrogen in the blood and for indican in the blood, simultaneously with the determination of the nitrogen and the indican contents of the urine. The nitrogen in the urine as well as in the blood was determined after the Kjeldahl method, the indican determination in the blood as well as in the urine was made according to the quantitative colorimetric method of Jolles.

The cases comprise: two of acute nephritis; seven of chronic nephritis; seven of nephrosis; thirteen of nephrosclerosis, two benign, and eleven malignant; one tuberculosis of the kidney; twenty passive hyperemia of the kidney; three of uremia, one of hypertonia; one of hypernephroma; total: fifty-five kidney cases. There were nine cases of diseases of the liver; twenty-two cases of primary heart affection (most cases included in these are of passive hyperemia of the kidney), fifteen cases of gastric and intestinal diseases, four cases of pernicious anemia, one case of leucemia, two cases of lead poisoning, four cases of emphysema, two cases of pulmonary tuberculosis, one case of fetid bronchitis, two cases of diabetes, one case of mediastinal tumor, one case of myxedema. Total: forty-one cases.

1. The relationship between azotemia, indicanemia, and indicanuria. The assertion of Rosenberg's that increased indican of the blood is produced by azotemia is not in accordance with my findings, because I have found increased blood indican in spite of a normal amount of residual nitrogen in the blood. This fact refutes Rosenberg's assertion that increased azotemia is responsible for increased blood indican.

2. Rosenberg's statement that increased blood indican is caused by resorption of indican, formed in excessive amounts within the intestinal tract, is also refuted because I found excessive amounts of indican in the urine and only little indican in the blood of the same person; on the other hand I found excessive blood indican and only little urinary indican in other cases.

3. Indicanemia, therefore, is not caused by increased azotemia in nephritics nor is it caused by increased formation of indican within the intestinal tract, but it is caused by retention. This retention in the blood takes place because the diseased kidney tissue meets the various nitrogenous products, des-

**Die Indicanemie ihre Bedentung als Nierenfunctionsprobe.* Urban & Schwarzenberg, Wien-Berlin, 1922.

tined for elimination, with various specific secretory difficulties; among these nitrogenous metabolites in the blood, indican happens to be the one the elimination of which the kidney rebels at first. It is possible (as E. Becher shows by his experiments on the distribution of indican in the various parts of the body, under normal and pathological conditions) that the indican which had been retained within the blood, on account of renal insufficiency, accumulates mostly in the blood, while only a little of it penetrates into the tissues, this in contradistinction to residual nitrogen and especially urea. This may account for the relatively large increase of blood indican compared with the increase of residual nitrogen and urea in the blood; it may also account for the retention of indican in the blood which takes place much earlier than that of the residual nitrogen and urea in the blood. This explains the cases where we find increased blood indican but still normal residual nitrogen of the blood.

4. In the various lesions of the stomach and intestines, we found blood indican values ranging 0.08-0.8 mg. per cent. We could not find any relation between these blood indican values and the urinary indican values; on the one hand we found increased blood indican in patients who exhibited only small urinary indican values while on the other hand we observed small blood indican values in spite of enormously increased urinary indican values. These observations do not conform with the statement of Georg Haas who reports as his highest blood indican value in the stomach and intestinal diseases 0.147; inasmuch as Haas precipitates the serum albumen with alcohol, while I, just as Rosenberg, used trichloracetic acid, I had to multiply the values found by Haas by 1.6—according to Vanbœmmel's suggestion—to conform my findings to those of Haas's, but even then, after such correction, I got higher blood indican values, in cases of peritoneal tuberculosis for instance. This fact corroborates rather Rosenberg's finding of blood indican values up to 0.2 mg. per cent., in cases of intestinal diseases, without renal affections. I do not believe that the increased blood indican values found in gastric and intestinal affections were due to the increased putrefaction within the intestinal tract because there are cases of large tumors and frequently bleeding ulcers among the cases with increased blood indican. Besides, as I have pointed out, there is no interrelation between blood indican and urinary indican.

5. Three cases of pernicious anemia (verified at postmortem) showed blood indican 0.16 and 0.80 mg. per cent. The residual nitrogen of these cases was always above the normal. As I have pointed out in my book on indicanuria (1912), the urinary indican in such cases is always increased; but that the blood indican in such cases is also increased, is a new fact which I wish herewith to state.

6. We do not find blood indican values above 0.24 m.g. per cent. in people with normal renal function (except in stomach and intestinal diseases and pernicious anemia), in spite of excessively high values of their urinary indican.

7. Four cases of emphysema exhibited normal blood indican values.

8. Three cases of lead poisoning without nephritis, exhibited normal blood indican values, though the urinary indican was excessively high in two cases.

9. Two cases of diabetes showed normal blood indican values.

10. Of nine cases of liver disease only two showed blood indican values above 0.16 mg. per cent. These findings are in contradiction to Rosenberg's statement that liver diseases frequently cause higher blood indican values.

11. Of two cases of acute nephritis, one showed blood indican above 0.16 mg. per cent. The indican values of the blood proved to be a much more reliable test for the renal function than the determination of the residual nitrogen in the blood.

12. In seven cases of chronic nephritis we found the blood indican always increased whenever the residual nitrogen in the blood was increased; but one can not say that the blood indican always diminishes whenever the residual nitrogen in the blood diminishes, because one frequently observes the blood indican increased in spite of a decrease of the residual nitrogen, one even finds blood indican values already increased while the residual nitrogen is still normal. On the other hand we never found normal blood indican with an increased residual nitrogen in the blood. In other words: The blood indican level increases more quickly and sooner than the residual nitrogen level, especially when the condition of the patient, clinically, becomes worse. All these findings conform with the findings of Georg Haas. The dilution and concentration test proved, in this group of cases, of equal diagnostic value to the quantitative test for blood indican; they were, however, just like the blood indican test, diagnostically superior to the residual nitrogen determination in the blood.

13. The seven cases of nephrosis all showed a normal blood indican level. The residual nitrogen test in this group was also normal.

14. The cases with hypertension were subdivided into, 1, those without albumin and without edema, five cases; 2, those without albumin and with edema, two cases; 3, those with albumin and without edema, six cases; and 4, those with albumin and with edema, one case. With due consideration of the clinical symptoms and the water test findings one can determine whether this hypertension is a, benign, or b, cerebral arteriosclerosis, or c, renal arteriosclerosis. The renal arteriosclerosis may be subdivided into a benign and malign nephrosclerosis. The blood indican values always denote the seriousness of the kidney lesion.

15. The relation of cardiac insufficiency and blood indican. The passive hyperemia of the kidney, produced by heart insufficiency, exhibits, at the beginning, normal residual nitrogen as well as indican values in the blood, regardless of whether the case presents edema and ascites or not. In the course of cardiac insufficiency, there takes place first an accumulation of residual nitrogen in the blood while the indican level still remains normal; in the further course, after a prolonged and repeatedly returning passive hyperemia has brought about a stasis nephritis, the indican level of the blood also increases. Later, when through therapeutic measures a profuse diuresis has taken place, the residual nitrogen in the blood may drop to normal, but the persistent increased blood indican will denote the permanent kidney lesion. If one finds, in a clogged kidney, norma

residual nitrogen, but increased blood indican, one must always suspect a kidney lesion. Thus the indican test on the blood becomes of great value for the differential diagnosis between cardiac and renal dropsy.

16. Through the kindness of Professor Eppinger, I had occasion to examine separately arterial and venous blood, received at the same time from the same patient. The residual nitrogen in the venous blood, in the four cases examined, always showed higher values than in the arterial blood; the indican value was higher in the venous than in the arterial blood, only in two cases (in the other two cases it showed no difference in value), perhaps due to the limitations of the colorimetric test. The higher values in the venous blood suggest the existence of metabolic indicanemia.

17. Of the ninety-eight cases observed, twenty died; the postmortem examinations corroborated the clinical observations made.

To enable the general practitioner to carry out the indican test on the blood, it is sufficient to use the following technic for the qualitative test because even the slightest purple discoloration of the chloroform in the qualitative test carried out with the indicated quantities of serum and test solutions is a positive indication of an amount higher than 0.16 mg. per 100 c.cm. serum, which means supernormal value of indican in the blood. The latter denotes always a permanent lesion of the kidney in all cases of hypertension.

INDICAN BLOOD TEST

Two test tubes.
Into tube I place 2 c.c. blood serum.
Into tube II place 1.5 c.c. serum.
Into tube I add 2 c.c. distilled water.
Into tube II add 1.5 c.c. distilled water.
Into tube I add 4 c.c. of twenty per cent. trichloracetic acid.
Into tube II add 3 c.c. of twenty per cent. trichloracetic acid.
Shake well and filter.
Add to each tube seven drops of five per cent. alcoholic thymol solution.
Shake well.
Add to tube I 8 c.c. of HCl solution.
Add to tube II 6 c.c. of HCl solution.
Shake well.
Let stand two hours and then add to each tube 2 c.c. of chloroform and shake thoroughly.
Slight purple discoloration of the chloroform is indicative of abnormal amount of indican in the blood.

SOLUTIONS NECESSARY FOR BLOOD INDICAN TEST

1. Hydrochloric acid 100 c.cm.
   Ferri chloride 0.5 grams
   Prepared fresh every week!
2. Thymol 5.0 grams
   Alcohol 100 c.cm.
3. Trichloracetic acid 20 c.cm.
   Distilled water 100 c.cm.

Periodic Physical Examinations for Physicians

OTTO H. LEBER, M.D.
New York

A close observer of articles pertaining to public health in the last few years must have been struck by a note sounded in them with increasing frequency, namely, that of periodic physical examinations for people supposedly in good health. With little notice taken of it at first, this idea has grown and taken greater hold year by year, until with its recent recognition by the American Medical Association a stamp of approval was placed upon it that must go a long way towards materially increasing the annual number of such examinations. No better proof of their practical advantage is needed, than the action of large life insurance companies in spending vast sums of money each year in gratuitously furnishing annual examinations, having satisfactorily proved to themselves that they are thereby lengthening their policy holders' lives and so putting money into their own pockets.

Left neglected for a long time, this field of endeavor for practising physicians has too long remained unused, and in the face of a falling mortality and morbidity rate automatically tending to lessen the physician's practice and his income, it should, and properly, initiate an increased activity in preventive medicine where amelioration and therapy have ceased to be necessary.

But we must practice what we preach, and my plea at this time is not so much enlarging this field in our practices, as pushing the adoption of this habit among ourselves, and propagating the idea among the medical profession at large. Since this idea has taken hold in my mind I have been observant and questioning among my fellow physicians, and find, as a general thing, such a shocking neglect of their own physical welfare as would call forth the greatest condemnation on our part were these individuals our patients; to say nothing of an apparent reluctance and neglect to avail themselves of those very medical services the value of which it is our daily business to advocate and impress upon the community at large. So far as periodic physical examinations are concerned, I have also yet to find a physician who while in supposed good health has ever submitted to one himself, if we except those compulsory and often incomplete and unsatisfactory examinations required by life insurance companies, the civil service, or those taken for admission to the military service. How to explain such a unanimous abstention of an admittedly beneficial practice I must admit I am at a loss to know. On the face of it, of course, a physician, better than anyone else, one would suppose, ought to be able, in a large number of cases at any rate, to note the early symptoms in himself of a very large number of diseases. But whether he is too close to get the proper perspective, too busy, or too careless, suffice it to say that far more notice would be taken of them if called to his attention by a fellow physician in the course of a painstaking examination. Again, there is something about high blood pressure, heart murmurs, albuminuria and a

host of other unpleasant physical signs, that a physician, quite willing to impart to others, is most loath to hear about when applied to himself. So important is this factor in my estimation, that the entire success of these examinations depends, in my opinion, no more upon the skill of the examining doctor as it does upon his common sense, his perception of the psychology of his patient and his ability to impart truth without having go with it a sense of haunting fear and worry that will accompany his victim from one examination to the next. I think that it can honestly be said, however, that this neglect is not due to any lack of confidence in his own wares, as it is to the peculiar psychology of the medical man's mind that proverbially makes him a bad patient. Admitting therefore as every physician does with whom I have conversed on the subject, that such periodic examination carefully carried out is of distinct value in prolonging a physician's life, and in promoting his efficiency, what measures are we to take to make this a movement sufficiently large in scope to really be of distinct value to a large proportion of our profession as well as a public health measure of considerable importance? The following it would seem would be some of the steps that ought logically to be taken:

1. The proposition should be broached and made the subject of discussion at all medical meetings.

2. The fullest publicity to the subject together with editorial comment in, 1, all medical journals that do not limit their pages to scientific papers exclusively; 2, similarly, and with quite as much importance, in whatever lay publications as would seem desirable.

3. The adoption of the idea by the leading men in the profession and officers of the various medical societies to the extent of setting an example and having such examinations performed.

4. The adoption of the principle even though it be among our own profession, of charging a fee for this service, and perhaps best, a definite and fixed one. Even though it is of course the recognized custom that physicians should not charge one another for services, it seems to me that when one considers this plan there occur to one a sufficient number of reasons why it might succeed better if it were universally understood that a regular fee were to be charged and accepted for such health examinations quite apart from the customary gratuitous services during an illness. Such a custom would without doubt result in a freer and wider choice of physicians, certainly most desirable, and a tendency to give and a right to demand greater thoroughness than might otherwise be expected between two friendly confrères. There is plenty of time to consider the amount this fee had best be, but ten dollars seemed to me as mutually reasonable as any, and could be considered quite a fair and proper annual charge for health insurance.

By working along these lines, I think, we can set in motion what might well be a popular movement of considerable proportions, which with the large amount of publicity, and the good examples set, might result in sufficient unanimity of action to go on with its own momentum and with the knowledge of its own good from year to year.

I say "might" advisedly, for there have been many causes and movements, which without a logical or proper argument against them, have failed for reasons of lack of urge, general lethargy or other reasons indefinable. And so I have wondered whether this cause could not be hastened by devising a formula if you will, to facilitate the early adoption of the plan by large numbers, rather than to wait upon the long drawn out effect of education alone.

This formula would be, first, the adoption in principle of this plan by the various county medical societies, to be followed by the inclusion in the annual dues of these societies of the fee for such examination for each member. I approach the suggestion of such a radical step as this advisedly and with full knowledge of the probable opposition such a proposal would be met with in these societies. But when I face the alternative, which I feel, like in so many other cases would be, quite universal approval, with at the end of each successive year quite as universal neglect as before, I then approach the subject with more boldness and less trepidation in the confidence that the medical profession will not hesitate to take a bold step when the ultimate goal fully warrants it. If adopted, the further method of procedure after this would have to be carefully worked out, but it should certainly call for free choice of examining physician, and might also call for direct payment of the examiner by the county medical society.

I do not wish to close this subject without making reference to what may be termed secondary effects of its success and which rival in importance the first proposition. This movement can hardly attain any large measure of popularity without almost of necessity including the various members of the physician's families and their households to the extent of their also adopting the practice and so directly increasing our welfare and happiness. We have here then a proportion of population which cannot be ignored in its size and in its power to preach and promote this healthy doctrine in the most far reaching way. Moreover what possible objection could there be after a universal adoption by ourselves for our organized state and county organizations and periodicals to push in a real and militant way by lecture, poster or advertisement in dignified yet forceful manner this doctrine and its power for public good among the population at large with a resulting increase in respect, importance and standing of the medical profession in the eyes of the public.

To sum up then, I am advocating a periodic, preferably annual, physical examination for physicians, to be advocated in a campaign of education in medical societies and in the medical and lay press for the promotion of the improved health, greater longevity and increased efficiency of ourselves.

The general adoption of this project by the rank and file of the medical profession should in addition go a long way toward making it plausible for us to stand before the public and advocate its universal acceptance and practice. The universal adoption of this practice by the public would be a forward step in public health education of the foremost magnitude and result in material benefit to the practice of medicine in general.

The Romance of Medicine

Presidential Address

WILLIAM D. HAGGARD, M.D.

Nashville, Tenn.

"Taught by art divine the sage physician eludes the urn, and chains or exiles death."

The story of medicine enthralls the imagination by its infinite charm and arouses admiration for its victories in the battles against disease.

Its romance is so compelling that men cannot be unmoved by its blessings, when they realize with us its splendor. The records of the discoveries of medicine are more fascinating than fiction; their marvelous benefits are as if in response to Jeremiah's lament, "Is there no balm in Gilead, is there no physician there?"

The price of these great benefactions is beyond all the rubies of the world; it can never be computed and it can never be paid. In the Middle Ages the average life of man was twenty-odd years. Now the span has been increased almost threefold. Compute if you can the growth in economic value of a human life extended to this lengthened expectancy and worth an ever increasing yearly wage. Compute the value given by bestowing these benefits to all the nations of the world. If you can estimate these things, only then will you have totalled the economic wealth contributed to mankind by this incomparable service. And in the precious years that have been added to the span of life, countless days of unhappiness and suffering have been eliminated. Innumerable ills have been parried from the feeble flesh of man. What a glorious thing it is when the piteous procession of men and women beg of you to be allowed to live a little longer on any terms, that you can succor them by the knowledge of Nature's secrets that are your heritage from the studies of the scholars of all times.

W. D. HAGGARD, M.D.
President, American Medical Association, 1925-26

Wonderful as the past has been, the last fifty years of medicine have witnessed more achievements of a miraculous character than the five preceding centuries. This is the golden age of medical advancement. Discoveries of transcendent import have trooped on us in bewildering profusion. Allusion to some will suffice to give a glimpse of the glamour by which all are pervaded. The last century gave us ether and chloroform, by which, as Oliver Wendell Holmes said, "the fiercest extremity of suffering was steeped in the waters of oblivon and the deepest furrow in the knotted brow of agony has been smoothed away forever." Antisepsis has revolutionized surgery and made possible the present proud perfection of that most brilliant of all the arts. Mathematically, it has reduced the death rate from all amputations from 65 per cent. in Paris in 1861, to 4.5 per cent. in Pennsylvania today. Among its many almost incredible feats is now recorded a successful effort to cut the shortened cords inside the heart itself, and allow the fettered valves to close again securely. Although the heart is only one inch from the surface of the body, twenty centuries of surgery rolled by before the scalpel could travel that inch.

Medicine is the only profession that is literally and altruistically devoted to professional suicide. It endeavors chiefly, not alone to cure, but to prevent disease, and thus to banish from mankind pain, suffering and ultimate death from maladies of the flesh.

But what it cannot prevent it must cure. What it cannot cure it must palliate. Angina pectoris, the merciless, is now being attacked surgically and the heart pang relieved in certain cases by severing the sympathetic nerves in the neck that transmit the unendurable pain.

The discovery of the germ of tuberculosis, "the Captain of the men of Death," was the beginning of the annihilation of the Great White Plague and is a more important victory for mankind than resulted from the Fifteen Decisive Battles of the World. Already the death toll has been reduced from 160 per hundred thousand in 1910 to 97 per hundred thousand in 1922. But the fact that even today every third minute on the clock's dial marks a death from tuberculosis challenges us to still greater efforts. It is now largely a social problem. As the contagion for the most part comes from the lungs and mouth, we must teach everybody not only to burn expectorations, but to avoid this contagious material in every possible way. We must prevent, rather than be faced by the necessity of attempting later cure.

That the spirochete was the actual cause of syphilis, the great Black Plague, was discovered by Schaudinn in 1905. Miraculously enough, in the next year Ehrlich discovered that his six hundred and sixth experiment with arsenical compounds gave the present arsphenamin, with power to stay its ravages.

A romance in medicine to grip the admiration of the world is the subjugation of typhoid fever. In the Boer War, typhoid destroyed 8,000 British soldiers, while only 7,000 were killed by all the enginery of Mars. In the World War, as a result of antityphoid vaccine, which was given to each of our 4,000,000 American soldiers, and increasing knowledge of sanitation, only 1,083 cases of typhoid fever developed, with only 158 deaths. If the ratio between enlistments and deaths from typhoid in the American Civil War had been maintained in the World War, there would have been some 226,000 cases, with 62,694 deaths. This conquest of typhoid is one of the greatest benisons of modern medicine.

Under a picture that was current recently, of a fervent minister, robed and with upraised hand, was the legend "Preaching to beat Hell." We, as ministers of health, must also unceasingly preach—preach pure water, fresh air, sunshine, sanitary environment, plain, wholesome food, exercise and right living—to defeat the powers of darkness and bring the purity of heaven to earth.

Most dramatic among modern victories is the conquest of yellow fever, the scourge of the Spanish Main, "the pestilence that walketh in darkness; . . . the destruction that wasteth at noonday." An epidemic of this in 1793 took the lives of 10,000 people in Philadelphia in three months and kept the Southern states in consternation with the recurring seasons. Its devastation prevented the genius of France from building the Panama Canal across a zone which for four centuries had been called the "white man's grave." The indomitableness of Roosevelt was matched by the genius of Gorgas, the master of yellow fever, who made of the charnel hole of Panama the healthiest spot on earth. Thus occurred the union of the oceans through the canal.

In the opening year of the twentieth century, Reed, Carroll, Lazear and Agramonte proved, through the peacetime bravery of American soldiers who bared their bodies for the fateful experiments, that a mosquito transmits yellow fever. While experimenting with deathladen Stegomyia, one of these army surgeons was bitten on the hand and sacrificed his own life in the consuming passion to save his fellow man. No man hath greater love than this. As Agramonte said of him, "One more name, that of Jesse W. Lazear, was graven upon the portals of immortality." Is it immodest for us in recounting this heroic self-sacrifice to have the pride of guild and to regard proudly the noble deeds of our profession?

In the last decade, many diseases of the heart, kidneys, gallbladder and other organs have been shown to be derived frequently from the foci of infection around the teeth, in the tonsils, in the sinuses of the nose, and in other structures. This great discovery has enabled the physician to administer in many cases the most effective of all treatments, the removal of the cause. Rosenow has taken the infectious material from the vicinity of stone in the kidney and, by implanting it in a cavity drilled in the healthy tooth of a dog, has been able to produce stone in the dog's kidney in eighty-five per cent. of the cases. By injecting into the veins of a rabbit's ear material taken from an infected appendix, from ulcer of the stomach, and from inflammations associated with gallstones, Rosenow has also been able to reproduce the disease in the organ from which it was obtained. This experimentation seems to show the specificity of certain microorganisms for regularly attacking the same structures, under definite conditions. We know, for instance, that the agent in infantile paralysis gains access through the nasal cavity and lodges in the anterior horn of the spinal cord. Prevention or even eradication of diseased foci thrice arms the physician of today for the throttling of many insidious diseases or, if they have gained headway, their amelioration or cure.

The recovery of radium by Madam Curie close on the discovery of the röntgen ray by Röntgen in 1896 was not only a triumph in wresting another secret from the physical world, but has furnished a most necromantic weapon for the cure of certain forms of cancer and for its palliation in hopelessly neglected cases.

The use of safe drugs for local injection in rendering surgical operations painless is now like a performance in a world of magic. Antitetanic serum to prevent lockjaw is the king of preventive serums. Practically every battle casualty in France was potentially infected with lockjaw. Every wounded man that came back from the front had A. T. S. (antitetanic serum) pasted on his forehead. The universal use of the serum mercifully prevented the terrors of lockjaw.

The transfusion of blood into the veins of those who from injury or disease are sickened into the whiteness and coldness of death quickly brings back the glow to the check and the red lipped promise of reclaimed life. This boon was made possible by the discovery by Mall, of the four types of blood; the use of an untyped and dissimilar blood group donor is most dangerous.

We physicians and the whole world are daily

Swan-Myers

RAGWEED POLLEN EXTRACT

A Stable Glycero-saline Extract for the Prevention of Fall Hay-Fever

A Product of the SWAN-MYERS BIOLOGICAL LABORATORIES at Indianapolis, Ind.

The extract is prepared from 50 per cent. short ragweed pollen and 50 per cent. of the pollen of the giant ragweed. The pollens have been collected by our own botanist and have fully matured on the plant before the harvesting. They have been freed from extraneous matter, dried over sulphuric acid and preserved in the dry state until the extract has been prepared.

The extracting process is accomplished with a menstruum of 67 per cent. C.P. glycerin and 33 per cent. saturated salt solution to assure the maximum stability of the resulting product.

Each dose has been accurately measured by units into a separate vial to be diluted at the time of injection. The extract will remain potent in this undiluted form for at least twelve months after leaving the laboratory.

Undoubtedly the cause of failure of hay-fever prophylaxis in the past has been largely due to the fact that aqueous, alcoholic and saline extracts have been used.

SWAN-MYERS RAGWEED POLLEN EXTRACT

Dose No. 1 contains 2.5 pollen units.	Dose No. 9 contains 150 pollen units.
Dose No. 2 contains 5 pollen units.	Dose No. 10 contains 240 pollen units.
Dose No. 3 contains 10 pollen units.	Dose No. 11 contains 350 pollen units.
Dose No. 4 contains 20 pollen units.	Dose No. 12 contains 500 pollen units.
Dose No. 5 contains 35 pollen units.	Dose No. 13 contains 700 pollen units.
Dose No. 6 contains 50 pollen units.	Dose No. 14 contains 1000 pollen units.
Dose No. 7 contains 70 pollen units.	Dose No. 15 contains 1000 pollen units.
Dose No. 8 contains 100 pollen units.	

	Price	Code
Series I contains Doses 1 to 5 inclusive with the accompanying vials of diluent	$ 4.25	Admix
Series II contains Doses 6 to 10 inclusive with the accompanying vials of diluent	4.25	Atilt
Series III contains Doses 11 to 15 inclusive with the accompanying vials of diluent	4.25	Avens
Complete Treatment contains fifteen doses with the fifteen vials of diluent	12.00	Armor

SWAN-MYERS COMPANY

Pharmaceutical and Biological Laboratories

INDIANAPOLIS, IND., U. S. A.

A Few Facts

The immunization treatment usually consists of fifteen graduated doses, and these may be given in as short a time as five weeks, allowing three doses for each week. Much better results have seemed to follow the less intensive schedule of dosage. It is suggested that fifteen weeks be allowed for the treatment and that the patient receive one dose each week. The series should be completed about a week before the time for the expected onset. Thus if a patient's hay-fever usually starts on August 15th, the treatment is ideally started on May 2nd or as soon thereafter as practicable.

"In those localities in which the ragweed is found, about 85 per cent. of all the cases of autumnal hay-fever are caused by ragweed pollen." From the book by Dr. Wm. Scheppegrell, President American Hay-Fever Prevention Association, "Hay-Fever and Asthma" (1922).

"Active immunization" (with pollen extracts) "offers hay-fever victims more chance for cure and relief than any other therapeutic measure." Dr. H. S. Bernton, *Journal American Medical Association*, May 5, 1923, page 1307.

Swan-Myers' Ragweed Pollen Extract is accepted by Council on Pharmacy and Chemistry, American Medical Association. See page 258 in "New and Non-official Remedies" for 1924.

debtors to the innumerable instruments of precision, to the blood pressure apparatus, the basal metabolism rate machines, and the newer instruments for administering gases, that render anesthesia almost totally devoid of danger.

What is more astounding than the revelation in the last few decades of the part played in our bodies and lives by the wonder working ductless glands? They send weird and powerful hormones as chemical messengers to command the functions of the body. The thyroid gland presides over our growth; its absence makes the gnomelike grotesque idiot, the cretin. Administration of the lifegiving thyroid extract veritably restores the dead in mind and brings dwarfed bodies back to blooming youth. Compared to these realities, legends of old time restoration of the dead are but interesting myths.

It seems incredible that the pituitary gland at the base of the brain, weighing only two grams, will, when diseased, cause the prodigious growth of a giant, and when its secretion is deficient produce the enormous fat deposit of the pathologically obese.

The greatest romance of the last few years in medicine was the discovery of insulin by Banting. The wizardry of rescuing the diabetic patient by this remarkable discovery is truly a marvel.

Goitre is largely due to a deficiency of iodine in food and water. While it can be successfully removed, with an infinitesimal death rate, it should be prevented in childhood by the administration of iodine in small quantities to children twice a year. These wonderworking ductless glands largely determine personality. Individuality seems, after all, to be largely the product of the chemistry of our bodies.

Passing from the intangible to the practical, we may note that the solution of the pellagra problem seems nearer with the increasing belief that pellagra is a deficiency disease, possibly from a shortage of vitamines, and seems to be caused by faulty protein food mixture and is greatly benefited by fresh meat and milk. These and other contributions of medicine to the relief of humankind are more thrilling to the man of science than all the wars of selfish kings.

I am not an unqualifying eulogist of the profession of medicine; I am but telling the plain, unvarnished truths that constitute the romance of our great calling. Like every sublunary institution, that of medicine is subject to evils, many of them common to it and other professions, and many others pertain to it alone. We are prone to be overenthusiastic about each new advance; on the other hand, many of us are as unable to evaluate the worth of a fresh discovery as was Joseph Bell (the original of Sherlock Holmes) to recognize the solemn significance of antisepsis, as advocated by Lister, albeit he was his daily colleague in the wards of the Glasgow Infirmary.

It may not be regarded as romantic, and therefore within the realm of this paper, to recall that the cause of typhus fever is the bite of an infected body louse; but when one thinks of the terrifying epidemics on sea and land which have been stamped out by this knowledge and by sanitation, our medical accomplishment rises, not only to the romantic, but to the sublime. Likewise the most fatal of all infections, plague, bubonic and pneumonic, is transmitted to man by the flea that has bitten the infected rat. The extermination of the rat to prevent it and Haffkine's vaccine to cure it is a historic achievement. Rocky Mountain spotted fever has been shown by Ricketts to be transmitted by the wood tick.

The most threatening cloud of chronic disease in the South, hookworm, has been dissolved by the wand of Aesculapius. Through the labors of physicians and the beneficence of the Rockefeller Institute, the weakened, anemic, shiftless "poor white" has, by the use of thymol, been freed from the parasite. There is yet so much to discover. It requires a vision and endless, patient, animal experimentation. Claude Bernard said that whenever he left his laboratory he put on the cloak of his imagination in order to know where next to look, through experimentation, for Truth. The microbic causes of smallpox, of measles, of mumps, of chickenpox and of the much dreaded encephalitis (socalled sleeping sickness) are as yet undetected. And many chronic diseases are still eluding an accurate analysis and a cure. Lest we be vainglorious, let us hasten to remember that there is as yet no specific for pneumonia, which, with the other acute respiratory diseases, destroys more lives every day than any other one ailment.

Cancer, the most pitiless of all maladies, is our rebellious and still elusive foe. It has not yielded up its murderous secret. We know all about its life history except the very beginning. It is regularly curable in its first stages, in many cases by surgery, in many by radium, and in others by the roentgen ray; but its bacterial causes, if such there be, still elude the patient investigator. The honor and benefit of this great discovery is more to be desired by the physician than the wealth of Midas, the wisdom of Solomon or the glory of Napoleon.

The fiery serpent that bit the children of Israel when they wandered through the wilderness was possibly the guinea worm, which enters the body as a water flea, develops, and ultimately, lies coiled under the skin, from one to six feet in length. It formerly was coaxed out by winding it on a stick little by little each day. Then the zoologist found that it seeks water in which to lay its eggs, and will naïvely crawl out if the affected leg or arm is simply submerged in water for a few hours.

The mysterious is so simple when revealed by science! And so our learning advances little by little. Each of the myriad of discoveries for the protection of man against his environmental enemies is almost akin in comparative magnitude to the body of a single tiny coral insect in the great structure to which it contributes. Thus we rear the eternal structure of the Temple of Medicine.

PERIODIC HEALTH EXAMINATION

The real romance of present day medicine is to prevent or to discover early the degenerative conditions of the great organs, the heart, kidneys, liver and brain. All the saving in life has been in the prevention of infant mortality in the control of contagious diseases. Eternal vigilance of every individual by his physician is the price of lengthened life in the middle aged.

As civilization can be measured by the statistics of public health, so sanitation is an expression of humanitarian impulses coupled with intelligent and

AS soon as it was definitely established by medical and biologic research that air-cooled and water-cooled quartz lamps emit ultra-violet rays of markedly different therapeutic properties, the Victor organization proceeded to develop lamps which would enable hospitals and physicians in general practice to apply ultra-violet rays with the precision demanded in modern therapy. Victor air-cooled and water-cooled quartz lamps have therefore been generally accepted as the most practical devices of their kind for the intelligent treatment of many conditions common to every practice.

expert application of medical knowledge to the community. Preventive medicine has made phenomenal progress in recent years. Particularly is this exemplified in the unsurpassed efficiency of the American army from the point of view of health during the World War. It was the cleanest army the world has ever seen. There were required more than 35,000 of the flower of the American medical profession to make and keep it fit to fight. None but the regular practitioners of medicine were permitted to touch the bodies of the precious soldiers in cantonment or advanced sector; but the noncombatants were constantly attacked at home, as always, by bizarre methods of treatment, so called, of a type which, as Barnum said, the American people love.

Community health is much in advance of the prevention of illness in the individual. Physicians have been so busily occupied in the care of the acutely sick that they may have had little time and have given scant attention to those who are in apparent health. People in great numbers have been amazed, when resting securely in the supposed enjoyment of perfect health, to find that an examination for life insurance revealed some entirely unsuspected malady, such as Bright's disease, diabetes or heart disease, that could and should have been easily detected long before. One third of the people who die from heart disease or Bright's disease die before they are fifty years of age. Even apoplexy shows fifteen per cent. of its mortality under fifty. These three conditions cause more than one fourth of all deaths. By early detection and eradication of the causes of these fatal lesions, many unnecessary deaths can be prevented.

What does it profit a person to neglect his physical condition and the wonderful mechanism of his body, the temple of his immortal soul? All other machinery is thoroughly overhauled at regular intervals. Boilers are frequently inspected, lest they explode. We all, physicians and laymen, have ignored the tremendous importance of a periodic and thorough physical examination. We have thus neglected our patients and even ourselves. In Shakespeare's *Cymbeline,* the bard sagely remarks: "By medicine life may be prolonged, yet death will seize the doctor, too."

Have a thorough physical examination on your birthday! It should be a real survey of a man's physical as well as mental status. Why should not a yearly inventory be made by one's physician of his habits, environments, occupation and dietary? If this plan could become universal, it would be the best postgraduate course in physical diagnosis that our profession as a whole could take.

From the economic side, there could scarcely be a better and closer relation between the physician and his clientele. The actual care and completeness of the examination would be in such startling contrast to the inadequacy and makeshift examination by the irregular practitioners and cults that it would be an education to patients who are not now privileged to understand really the difference between a competent, regularly graduated high type physician and the man who without adequate preparation masquerades under the guise of a doctor. The humaneness of the thing would appeal to the patient who needs us to tell him how to keep well. We will utilize our skill in anticipating future disability. We shall be promoting the ever widening field of preclinical medicine, and shall at last come into our own, because in the interpretation of our findings and the laying down of rules of health and conduct we shall at last be carrying out the original meaning of the word "physician," which is teacher. We must learn to deal with the brutally healthy man who never thinks of anticipating disease and forgets what a tremendously intricate and wonderfully made machine he so woefully neglects. He is very confident, yet his apparently superb stamina sometimes plays him false by throwing him entirely off his guard and making him an easy prey for some insidious disease stealthily to take hold on him. The proverb says, "Honor a physician before thou hast need of him."

It is estimated that the number of cases of sickness in this country in a year is thirteen and a half million, costing the nation a billion dollars. It is astounding to think that there are 225 million days of sickness a year in the United States. If it were possible, by nation wide effort, to reduce the amount of sickness by twenty-five per cent., the total economic gain yearly would be around a quarter of a billion dollars. How can one estimate the worth in anguish relieved and death postponed? Prevention runs as a thread of gold through the fabric of medicine. Every time we prevent illness we not only preserve that one individual as a productive force, but also one or two persons who would be required otherwise to care for him. The military maxim that it is better to wound an enemy than to kill him is based on this idea.

The people should be taught that in truth there can no more be different "'schools" of medicine than there can be different schools of physics, or of mathematics or astronomy. There is nothing under the sun which is of proved value that has not and will not be used by the profession in the treatment of disease. All of chemistry, of sanitation, of serums, of massage, of treatment by radium, of surgery, and of application of drugs are at our beck and call. All are utilized in the treatment of diseases. Sane men will not follow a charlatan. But if any trustworthy guide, be he physician or layman, proves that a given remedy is of value in the treatment of diseases, we will utilize it and will honor him. We should not be compelled, however, as Zinsser remarks, to eat an entire artichoke in order to get a tiny bit of really edible substance. There are, regarding healing, many decidedly fractional truths. As to some of them, the term "half truth" is an unwarranted exaggeration. "Nay," said Lord Bacon, "we see the weakness and fragility of men in sickness, as they will often prefer a mountebank or witch before the learned physician, and therefore the poets were clear sighted in discerning this folly when they made Aesculapius and Circe brother and sister, both children of the Sun."

All nonmedical agencies are enthusiastic endorsers of health examinations. Life insurance companies quickly saw a great saving in the postponement of the termination of premium periods by early detection and correction in their beginnings of chronic and fatal maladies. And the persons insured also gain, for they have their lives conserved and their longevity prolonged. Social health agencies

promptly recognize a probable reduction in the cost to the public of care of the indigent sick, a wonderful increase in well being and freedom from painful and distressing illness, and a consequent great contribution to human happiness. Yet periodic health examinations are primarily a practising physician's direct obligation. Nothing is better calculated than they to bring about the continuity of the long established and mutually confidential relation of the medical profession with the community it serves. To be successful, however, the idea of health examinations would require a real campaign, with the laity cooperating.

Let us have a drive for the prevention of illness by making a survey of the apparently well and devising an inventory for right living and for properly planned hygiene for the needs of each individual case among our apparently robust patients—a drive to treat the incipiently sick while they can be cured.

We will treat the mind as well as the body. It will give the opportunity to ask that most important of all questions in the investigation of the chronic case; viz., "Are you happy? If not, why not?" Can any one give more sympathetic and sane advice about the abstruse mental and emotional problems of life than the resourceful, experienced, tactful physician? Is his not the buoyant, commanding personality by virtue of the peculiar oraclelike relation which he sustains to his patient to be the scientific and sympathetic Samaritan?

> Cans't thou not minister to a mind diseased,
> Pluck from the memory a rooted sorrow,
> Raze out the hidden troubles of the brain,
> And with some sweet oblivious antidote
> Cleanse the stuff'd bosom of that perilous stuff
> Which weighs upon the heart?

A health week should be established nationally by all the health agencies of this country, with the cooperation of every one of the 90,000 members of the American Medical Association. The press can be counted on to do its part, which is as essential as it is unfalteringly interested and helpful in all health movements. A manual for the examination is being prepared by the American Medical Association. Examination blanks can be obtained from the headquarters, making for completeness and uniformity. A copy of the examination might properly be given the patients for their information, and one kept by the physician as a permanent record. Last, but not least, is a well considered interpretation of the patient's needs, physical, occupational and mental; and comprehending advice may finally be given to meet his peculiar needs. While it is primarily a technically complete head to toe physical examination, it is more a stocktaking of the patient's physical condition and an annual audit for health guidance.

Kipling tells of a legend in which the gods stole the godhead from man, who was at that time a sort of deity. They agreed to hide it. The wisest of the gods, Brahm, hid this tiny, unstable light of the stolen godhead where man would never dream of looking for it—inside man himself. That has ever since been Brahm's secret and will always be until man himself discovers it. Can the physician not help him to find his lost godhead?

The stupendous advance in medical education in the last fifteen years reads like a romance. The United States contained 160 good and bad medical colleges, more than twice as many as the rest of the world. These schools have been reduced to eighty strong schools. The course has been doubled in the last three decades. More than one fourth of these schools are departments of state universities. Enormous endowments have made medical education the pampered favorite of private munificence. The medical schools of America can proudly take their place in the sun.

The supply of an adequate number of sane, resourceful, dependable physicians should have the solicitude of the profession as a whole, as well as of the medical educators. The fear has been expressed that we are overstraining our students, that the specialties are so fascinating and their teachers are so enthusiastic that too much time is devoted to them in the undergraduate years. These years should, in truth, be given to basic preparation. The student must in the four years in the medical school encompass all the broad, fundamental principles of medicine. The man who is going to become a specialist should wait until after his hospital internship and preferably some years in general practice before he takes up specialization. A specialty should be a postgraduate study, not a part of a student's first preparation.

The laboratory side also should not be overcultivated. Fundamentals should be stressed, but recondite experimental work omitted in the undergraduate course. Relatively few students are going to be purely research men, and comparatively few are temperamentally fitted for that service. It is impossible really to make of an undergraduate an expert in any of the laboratory sciences. An excess of laboratory instruction, to the deprivation of needed bedside work, will not best prepare the student for the treatment of the sick.

In this desirable correlation between the pure sciences and the clinical subjects, the student of anatomy and pathology should be brought in his first two years into contact with the patient, so that he will appreciate the relationship of his studies to the problems of disease. Much more interest would be evinced in chemistry and bacteriology if every student were early to be given a glimpse of his wonderful relation to the patient. Then later, when the purely clinical work is taken up, it is not wise to abandon the study of biochemistry and physiology. Regarding clinical work in England, the Council on Medical Curriculum has advocated the continuation in the clinic itself of anatomy, physiology, pathology and chemistry, as these apply to the problems of medicine and surgery there presented. In this country our clinical and pathologic conferences have the source of the greatest inspiration.

The new medical school of Vanderbilt University is entirely housed in the hospital, thus linking up the wards with the laboratories in an integral and intimate way. We feel that it will be a distinct gain. It will afford an unparalleled opportunity for the simultaneous study of the medical sciences and the patient. The pathological department will be a guiding centre. Fresh tissue and not merely postmortem of terminal processes will be studied. It will concentrate on the causes as well as the development of disease. With the close relation of the dispensary

and the hospital, the pathological department, where all the problems of the patient can be brought and where all the men can work as undergraduates, as interns, as residents and as members of the staff, it ought to foster a spirit of investigative interest in the patient that will be stimulating to the completest possible training.

Our British cousins speak of the American methods as encyclopedic theory, and say that our effort in diagnosis is to make such a thorough study of the patient's state that no cell remains unturned. The student must be taught, as urged by President Hadley, to distinguish between the possession of information and the power or habit of thought. There is no substitute for thinking. Knowledge is proud that he has learned so much; Wisdom is humble that he knows no more.

A physician who gets a good start on a limited original training may go further than his more erudite brother, but he will always be happier and more efficient if he is interested in the humanities. The student must not be allowed to get so interested in the disease that he forgets the patient.

The question of entering the student into practice at an earlier age is important. It is impossible to devote to preliminary preparation less than two years of college work in biology, physics and chemistry, and it is impossible to eliminate anything from the four year medical course. The hospital year is essential. The only chance to curtail the length of time would be by saving one or two years in the high school. This can be done by the four quarter school year and no compulsory vacation at an unchangeable time, thus saving one or two years for the student with medicine as his goal.

SPECIALISM

One of the greatest romances in the art of medicine has been the amazing growth and perfection of the specialties. A man with an adequate training and a wide knowledge of disease, who devotes his entire time and thought to the problems of one department of medicine or one group of organs, can arrive at a surpassing degree of excellence. Some of the most intricate processes of relief for disease and injury are practiced by the specialists with an almost uncanny degree of dexterity. The removal of foreign bodies from the lungs by the bronchoscopic method amounts to legerdemain. The skill that is amassed by employing methods of precision over and over again becomes truly miraculous. The accumulative experience begets wisdom and judgment and a choice of the methods that are the most effectual. The development of the specialties has been possible by the focusing of original and brilliant minds on problems that are beckoning for solution. Specialism is so alluring that it is impoverishing the personnel available for the laboratories and decimating the ranks of the general practitioner. It is astounding what the country doctor, unaided by the panoply of present day instruments of precision, accomplished by the use of his five senses and that other very essential sense—common sense. "All but eternal doom was conquered by their art."

One of the drawbacks of specialization is that it loses for the physician the personal touch and close contact with the family and with the acutely ill. The family physician has with the family during illness a personal, intimate, sacred relation which the specialist can never enjoy. The general practitioner must retake his former position of importance. The grander domain of internal medicine must remain steadfastly the soul of medicine, the centre of the color standard.

THE FAMILY PHYSICIAN

The family physician has ever been the bulwark of medicine. "He shall heal the nations and defraud the tomb." His has been the labor of love as well as a superb endeavor to combat disease and rout it from its citadel. He is confronted with the most desperate conditions and has with rare resourcefulness risen to his responsibilities. The intrepidity of the country doctor in the management of the emergencies of accident and disease, the perils of childbirth, and the mastery of conditions under the most adverse circumstances is unparalleled. His calling exacts, as Kipling said, the utmost that men can give—full knowledge, a steadfast hand, exquisite judgment and skill of the highest, to be put forth not at any self chosen moment but daily at the need of others. He knows how to gild the gloom of affliction's couch with the silver lining of Hope.

The pagans believed that the physician came from the god of music, since it was his province to keep in tune the harp of a thousand strings. The physician has been eyes to the blind, feet to the maimed, deliverer of the poor; he has caused the widow's heart to sing for joy, and has gained the blessings of him that was ready to perish. He has been the Good Samaritan, and has imitated the benevolent miracles of the Great Physician.

Who will write the epic of the family doctor? Would that a Shakespeare could weave his deeds of bravery, his tender sympathy, his discretion and tact, his cheerfulness and courage, his devotion and fortitude, into an immortal sonnet.

Oliver Wendell Holmes apostrophized the spirit of service:

> Charity is the eminent virtue of the medical profession. Show me the garret or the cellar which its messengers do not penetrate; tell me of the pestilence which its heroes have not braved in their errands of mercy; name to me the . . . practitioner who is not ready to be the servant of servants in the case of humanity, . . . and whose footprints you will find in the path to every haunt of stricken humanity.

Yours is a glorious privilege of "inscribing your memories not on perishable marble but in the living affections of your fellow men." The war trump, the muffled drum, the measured tread of armed men, and the musket shot pealing over the grave honor the death of the soldier, but the physician who meets his death battling for Truth in the great arena of Science passes often to an inconspicuous grave, mourned only by the few who knew his worth.

At the southern entrance of St. Paul's Cathedral stands a statue of Sir Astley Cooper, by Bailey, a beautiful commemoration of the unrivaled surgical reputation of this great surgeon and of his fame as a teacher. Who will erect a monument in bronze or stone to the family physician? Would it not be fitting to perpetuate symbolically the vision of his service and the splendid part that he has played in the pioneer civilization of this country? We have commemorated our statesmen, scholars and warriors.

What of the man whose life is spent in the interest of humanity, for preserving their lives instead of the ruthless destruction of their bodies? An unknown British warrior lies in the crypt of Westminster Abbey to commemorate the spirit, the bravery and the sacrifice of his fellows. Above him is inscribed:

They buried him among the Kings because he had done good toward God and toward His house.

The French have immortalized their unknown soldier under the Arc de Triomphe, typifying the unparalleled fervor, fearlessness and patriotism of the poilu; and we in America have enshrined our unknown soldier at Arlington. It is time that a monument be erected to the unknown family physicians—generations of them—in grateful acclaim of their unfaltering love of duty and ineffable devotion to suffering humanity.

The Scientific Proceedings

We present below abstracts of some of the more important papers read at the various section meetings.

SECTION ON PRACTICE OF MEDICINE

CHAIRMAN, DR. ELLIOTT P. JOSLIN, OF BOSTON.
SECRETARY, DR. E. S. KILGORE, OF SAN FRANCISCO.

Chronic Nephritis.—Dr. Henry A. Christian, of Boston, said that classifications of nephritis usually were very complex. Their complexity decreased their practical service in the clinic. Almost all had an anatomical basis and very often autopsy failed to show the anticipated anatomical lesion. Complicated classifications created a false idea of our knowledge of nephritis. A simple clinical grouping of patients with nephritis was suggested. Patients with chronic nephritis were subdivided into, 1, chronic nephritis with edema; 2, chronic nephritis without edema; 3, vascular hypertension progressing into nephritis. In group 1 hypertension was rare until the late stages, while in group 2 it was present throughout with very few exceptions, and in group 3 it was the first change noted.

Chronic nephritis with edema, the author said, meaning edema of renal origin, was actually a rare condition. Very few patients with chronic nephritis without edema gave any history suggestive of an onset with acute nephritis. Patients who had had acute nephritis were not more liable to chronic nephritis without edema than were normal persons who had never had acute nephritis. Patients with chronic nephritis without edema were actually patients with general vascular disease in whom the renal disease was but a local manifestation. This type of cases made up a very large percentage of those diagnosed as chronic nephritis (almost 1,600 out of 1,650 cases of nephritis).

There were many evidences of diffusely spread vascular disease, such as high blood pressure, changes in the eyegrounds, palpable peripheral vessels, evidence of calcification as shown by x ray, angina pectoris, cardiac decompensation, cerebral disturbance, nose bleeds, etc. In studying the vascular lesions the ophthalmoscope and the x ray had been of great service. Only relatively simple, bedside methods were needed for a satisfactory study of patients with chronic nephritis.

Hypodermic Digitalis Preparations.—Dr. Harold E. B. Pardee, of New York, presented a clinical study, with a lantern demonstration. He said that an attempt had been made to determine the potency of various commercial digitalis preparations recommended for intravenous injection. The method used was to find the smallest dose that would produce an effect upon the T wave of the electrocardiogram. This method had previously been tried by the author with different samples of tincture of digitalis, and been found a satisfactory way to measure their potency.

Digifolin, digitan solution, digalen and the Burroughs Wellcome tablets of amorphous digitalin had been tested and their potency found to be far less than that suggested by the manufacturers. The initial doses of these drugs must be from five to ten times that recommended, in order to produce powerful emergency digitalis effects.

With the minimal effective doses of these drugs, it was found that the T wave change does not appear until from six to twelve hours after intravenous administration. This is later than it appeared after large doses of tincture of digitalis by mouth. Evidently the absorption of a large amount of the drug from the intestinal tract affected the T wave more strongly than did the injection of the minimal effective dose directly into the blood stream. The application of these things to the dose of the intravenous preparations was discussed.

Is Arteriosclerosis a Hereditary Constitutional Disease?—Dr. M. A. Mortensen, of Battle Creek, Mich., called attention to the fact that arteriosclerosis was not a modern disease. Egyptian mummies had been found with sclerotic vessels. Mortality statistics of the last few decades had shown a gradual increase in arteriosclerosis and associated diseases, which made the subject of cardiovascular renal disease a vital one to the practitioner as well as to his patients. While the etiology of arteriosclerosis was widely discussed in medical literature, most authorities agreed that knowledge of it was still limited and uncertain and hence the author put the subject of his study in the form of a question. Infections, acute and chronic, excessive indulgence in protein food, tobacco, alcohol, coffee and even overwork, he said, had been advanced as causes of arteriosclerosis, but these factors, even to an extreme degree were by no means always productive of the disease nor did extreme abstinence save one from this condition. Because of this fact, he had for many years looked upon a cardiovascular renal disease as belonging to a certain type of persons having a predisposing tendency to degeneration of arterial tissues. Osler recognized the hereditary factor when he referred to the inheritance of poor arterial tubing unable to stand the wear and tear of the circulation. For this reason, he said, he presented observations on a large series of cases studied from the points of view of heredity and blood chemistry. The study included three hun-

dred cases of arteriosclerosis, two hundred healthy women, two hundred cases chosen because of blood uric acid being below 3.0 mgs., and two hundred with blood uric acid above 4.0 mgs.

His conclusions were as follows:

He believed that arteriosclerosis or cardiovascular renal disease was definitely hereditary, a fact which had been amply proved by careful study of family histories. Also by way of heredity an abnormal protein metabolism was transmitted, which was manifested by an increased uric acid content in the blood, and no doubt occurred long before any evidence of hypertension or renal disease could be detected. This increased uric acid in the blood suggested an inherited inability properly to metabolize protein, which might be endocrine in origin, or due to abnormal function of liver cells. Our best and most rational prophylactic measure as well as remedy was a basic diet, which necessitated a reasonably low protein intake.

Treatment of Bronchial Asthma.—Dr. Albert H. Rowe, of Oakland, Cal., gave a lantern demonstration of protein sensitization skin tests in the treatment of bronchial asthma and presented the following conclusions:

One or more protein sensitization skin tests were found positive in ninety-one per cent. of 234 cases of asthma. Treatment of asthma based on such reactions usually gave satisfactory results if full cooperation of the patient was obtained. Sensitization was usually multiple. Inhalants, including animal emanation substances, orris root, and pollens were the most frequent causes of asthma. Wheat, eggs, milk, and other cereals were in order of sequence the most common foods to cause asthma, though any food may be responsible. Asthma due to bacterial allergy alone was rare in our experience. Vaccine therapy was of value in bronchitis secondary to asthma caused by other protein sensitization. Operations on the nose and throat rarely cured asthma and should only be done after a thorough protein sensitization study. A change of climate to control asthma was unnecessary and not economical. Complete or marked relief had been obtained in approximately ninety per cent. of 234 cases of asthma.

Splenectomy in Banti's Disease.—Dr. Nathan Rosenthal, of New York, said that the fibroadenia of the spleen in Banti's disease appeared to be a hyperplasia of the reticuloendothelial system, the overactivity of which might be primary or secondary. The primary type was associated with a bleeding tendency, he said, owing to a diminution of the blood platelets. Purpura hemorrhagica might also occur. The secondary type was the result of thrombocythemia. Here the blood platelets remained permanently increased in number after splenectomy. Thrombosis of the veins occurred at frequent intervals. The results from splenectomy in the first type were better.

Nonsyphilitic Aortitis.—Dr. Lester Neuman, of Washington, D. C., called attention to the fact that this was not an uncommon disease, and was commonly overlooked. He said it was found at all ages, especially from twenty-five to forty-five years. The symptoms were usually dyspnea and precordial pressure, and pain after exertion. There was usually a systolic murmur, along the course of the thoracic aorta, visible supersternal pulsation, and sometimes a widening of the aorta which could be demonstrated. The probable etiological factors were infection and overexertion. Treatment consisted of the removal of all foci of infection, prolonged rest, and the administration of iodides.

Growth, Development, and Prognosis of Diabetic Children.—Dr. Elliott P. Joslin, of Boston, in his address as chairman of the section, presented a summary of the records of diabetic children treated with insulin over considerable periods of time, with special reference to their growth, their basal metabolism, and sexual development. He spoke of the probable prognosis, and made many valuable suggestions regarding the proper treatment of these children.

Incipient Hypothyroidism.—Dr. William H. Higgins, of Richmond, Va., in a clinical study of hypothyroidism, presented an analysis of a series of cases with only moderate reduction in basal metabolism and minor signs. These he contrasted with true myxedema and pointed out certain similarities to hyperthyroidism.

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

CHAIRMAN, DR. RUDOLPH W. HOLMES, OF CHICAGO.
SECRETARY, DR. CARL HENRY DAVIS, OF MILWAUKEE.

Tuberculosis of the Vagina.—Dr. Lawrence R. Wharton, of Baltimore, presented an interesting paper on this subject, with a lantern demonstration. He concluded that tuberculosis of the vagina was one of the rarest of all gynecological diseases; that it almost never occurred as the primary manifestation of the disease; at necropsy, in practically every instance, older tuberculous lesions had been found elsewhere. The vaginal lesion was not always secondary to tuberculosis of the uterus or Fallopian tubes; in fourteen of twenty-eight cases examined at necropsy, the uterus, tubes, and ovaries were normal. The treatment and prognosis depended upon the activity and extent of the associated tuberculous lesions. Tuberculous ulcers of the vagina rarely yielded to conservative treatment; excision was the procedure of choice. In every instance, however, the therapeutic problem was fundamentally medical and the patient should be treated from that viewpoint.

The author also presented a case from his own experience, and appended a reliable bibliography of the recent and most valuable articles on the subject.

Distribution of the Ovarian Follicular Hormone in Human Genital Tissues.—Dr. Edgar Allen, of Columbia, Mo., and Dr. J. P. Pratt, of Detroit, said the presence of an active substance in ovarian follicles was demonstrated by the substitution of extracts for certain phases of ovarian endocrine activity in the rat and mouse. Using this decisive physiological test and the "rat unit" as a standard, quantitative analyses had been made of ovarian tissues and tissues of pregnancy from several domestic animals and man. Human tissues tested included normal and cystic follicular contents and corpora lutea removed at operation at different periods of the menstrual cycle, three corpora excised during early

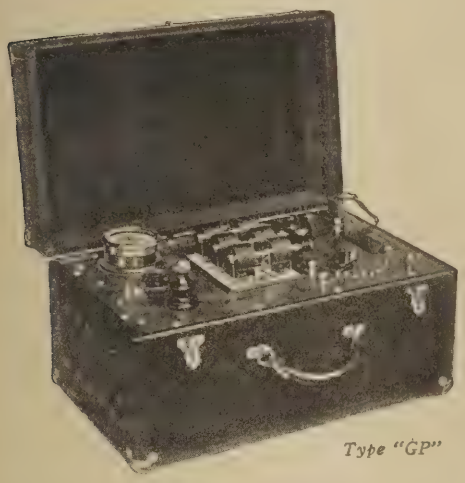
Fischer's Physicians' Portable Diathermy Unit—



Type "GP"

AN OUTFIT FOR EVERY PHYSICIAN

A truly "portable" outfit, designed for office or bedside use—sufficient power and range—all popular modalities—accurate in adjustment—easy to manipulate—neat in appearance—CAPABLE OF EXCELLENT RESULTS—light, compact, and efficient—and inexpensive.

Investigate to-day! Terms may be arranged if desired. Request demonstration in your own office by competent representative.

NO physician can read the wealth of medical literature on the subject of PHYSIOTHERAPY without instant realization of its great importance in his everyday work.

On every hand he finds the testimony of scientific men of its extreme usefulness.

And, as he investigates and comes to understand more thoroughly, the plain, everyday logic of it makes him act.

And when he acts, he soon becomes as enthusiastic as those whose reports have stimulated him.

In medical literature, at medical meetings, and in your everyday talks with brother physicians—it's PHYSIOTHERAPY!

What are you going to do about it?

H. G. FISCHER & CO.

2333-43 Wabansia Ave. Chicago

pregnancy, placentas at three and seven months and full term, and two intact embryonic vesicles. The authors reported that the human corpus luteum, unlike that of the pig and cow, continued the secretion of the follicular hormone in appreciable amounts for a considerable period following ovulation. Positive results from extracts of tissues of pregnancy might possibly indicate that the developing human embryo also continued the elaboration of this secretion.

Abdominal Surgery in Diabetic Patients.—Dr. Daniel Fiske Jones, of Boston, said that the diabetic patient with abdominal disease should be treated as a normal person, except in rare cases. This conclusion he said was reached partly because of the use of insulins, but more particularly because of the increased knowledge and experience of medical men in handling these cases. Team work between the medical man and the surgeon was necessary to obtain the best results. Abdominal emergencies were much more serious in a diabetic than in a normal person. Delay in these cases to give insulin was an unnecessary and dangerous procedure. The diabetic patient did not react to infection or to pain to as great an extent as a normal person; consequently delay was frequently advised, at great risk to the patient. To get a patient with a septic process in the abdomen sugar free was almost impossible. The author emphasized the importance of the use of insulin and a proper diet after operation in these cases.

Dilatation of the Ureter and Kidney Pelvis During Pregnancy.—Dr. Herman L. Kretschmer and Dr. N. Sproat Heaney, of Chicago, said that the cases they had studied divided themselves into two groups—normal cases without symptoms and cases with infection (pyelitis of pregnancy). They said that in normal cases, dilatation was found in nearly all cases examined. They discussed unilateral and bilateral dilatation, and the varying degrees of dilatation found, also variations in the course of the ureter. They stated that when infection existed, dilatation was found in every case. They noted that after delivery there was a rapid disappearance of dilatation. No constant pathological obstetrical factors were discovered.

Reducing the Surgical Risk in Some Gastrointestinal Conditions.—Dr. Thomas G. Orr and Dr. Russell L. Haden, of Kansas City, Kansas, said that several observers had noted an increase in alkalinity of the blood in pyloric obstruction; others had found an increase in the nonprotein elements of the blood. Acute pyloric and upper intestinal obstruction produced definite changes in the blood chemistry manifested by a fall in the chlorides, a rise in the carbon dioxide combining power of the plasma, and a rise in the urea and nonprotein nitrogen. The chlorides seemed to have some protective value in inhibiting or preventing the toxemia. Animals could be kept alive as long as thirty days with upper intestinal obstruction when treated daily with one or two per cent. sodium chloride. The same quantity of distilled water did not protect.

The authors stated that all acute intestinal obstructions should be treated with sodium chloride both before and after operation to reduce the toxemia. Sodium chloride might be administered either subcutaneously or intravenously.

Poor Surgical Risks.—Dr. William Thalhimer of Milwaukee, in a symposium on this subject, spoke of the laboratory aids used in preparing patients for operation and in caring for them postoperatively. He said that a patient was a poor surgical risk usually because of cardiac disease, renal disease, anemia, vomiting or diarrhea. Modern methods of examination easily determined the degree of cardiac and renal disease. The first was comparatively easy to diagnose and control. Renal disease was more difficult to evaluate, and even more difficult to treat after operation. Moderate or mild anemias were not given enough attention, even today, and transfusion should be used more often. Vomiting might be accompanied by either acidosis or alkalosis. With laboratory help each of these conditions was easily recognized, but they might be confused clinically. To treat the case properly, the exact condition must be diagnosed, as what relieved in one case, intensified in another. A lantern slide demonstration was given.

Distribution of Ovarian Follicular Hormone in Human Genital Tissues.—Dr. Edgar Allen, of Columbia, Mo., and Dr. J. P. Pratt, of Detroit, Mich., stated that the presence of an active substance in ovarian follicles was demonstrated by the substitution of extracts for certain phases of ovarian endocrine activity in the rat and mouse. In a former study conducted by Dr. Allen in collaboration with Dr. Edward A. Doisy (*J. A. M. A.*, lxxxi, 819) he found that the subcutaneous injection of liquor folliculi and extracts of follicular contents from ovaries of swine induced typical oestrus in spayed mice and rats. That definite degree of hyperplasia in the genital tract was found to be equal to the maximum attained in the normal animal under the influence of the ovaries. Three or four one c. c. injections of an active extract at intervals of four to eight hours returned positive results which were apparent forty-eight hours after the first injection. The application of a practicable test which could be followed in the living animal together with the short cycle of test animals had made these results definite and clear cut.

Using this decisive physiological test and the "rat unit" as a standard, quantitative analyses were made of ovarian tissues and tissues of pregnancy from several domestic animals and man. As far as the authors were able to ascertain, these were the first tests of this nature made upon the internal secretion of the normal human ovary.

Human tissues tested included the contents of normal and cystic follicles and whole corpora lutea removed at operation at different periods of the menstrual cycle, three corpora excised during early pregnancy, placentæ at three and seven months and full term, and several early embryonic vesicles.

Normal follicular fluid from human ovaries contained this active substance in concentration equal to or greater than that of pig ovaries. The human corpus luteum, unlike that of the pig and cow, continued the secretion of the follicular hormone in appreciable amounts for a considerable period following ovulation. Positive results were also obtained from extracts of certain of the tissues of pregnancy in man. Whether this meant an actual secretion by these tissues or a collection in them of hormone elaborated in the ovary was still an open question.

Coffee Without Caffeine

Coffee which lets one sleep
Coffee all may drink without stint

Kaffee Hag is pure coffee with the caffeine taken out. A selected and delightful blend.

The caffeine removal exceeds 95%, as shown by the analysis made of every batch.

The 72-hour process consists of opening the pores of the raw coffee bean and removing the caffeine. Nothing else is taken out save some coffee-wax and dirt. The aromatic oils are untouched. The flavor is not affected. Expert tasters cannot tell when the caffeine is removed. Thus the roasting of this coffee brings out all the aroma of the natural coffee bean.

Kaffee Hag is for people who should avoid caffeine. Or who must stint on coffee. Or who cannot drink coffee and sleep. It offers those people delicious coffee, pure, rich and fragrant, without the stimulation of caffeine.

Epicures almost the world over are now drinking Kaffee Hag. The finest hotels now serve it. The better stores supply it. So it means no hardship, no denial, when you advise Kaffee Hag.

We gladly mail to anyone who asks a ten-cup package free.

One will come to you with full information if you mail this coupon.

Packages will be mailed for trial to a list of patients, if you ask.

KAFFEE HAG

Pure coffee with 95% of the caffeine removed, as proved by analysis of every lot.

Ten Cups FREE

To Doctor or to Patient

Mail this with name and address to Kaffee Hag, 1476 Davenport Avenue, Cleveland.

SECTION ON UROLOGY

CHAIRMAN, DR. ROBERT V. DAY, LOS ANGELES, CAL.
SECRETARY, DR. GEORGE GILBERT SMITH, OF BOSTON.

Chairman's Address.—Dr. Robert V. Day, in his address as chairman, discussed the urological problems which the general practitioner, the internist and the surgeon encountered in their daily practice.

Value of Blood Transfusion in Surgery of the Prostate.—Dr. A. I. Dodson, of Richmond, Va., stated that blood transfusion was of special merit in the treatment of prostatic hypertrophy. These patients had reached the age when recuperation from injury was slow and many were additionally handicapped by anemia and sepsis. By increasing the volume and quality of the blood, thereby improving the general vitality and quickening the action of the bloodforming centres, blood transfusion was a most valuable adjunct to the preoperative care.

In a series of 147 deaths from prostatectomy collected by J. B. Deaver, Dr. Dodson said that hemorrhage and shock occupied second and third places as causative agents. It was in this class of patients that blood transfusion was of greatest help. The bloodvessels of many of these old men, because of sclerotic changes, were unable to adjust themselves to the rapid loss of fluid from the vascular system. There resulted a fall in blood pressure which frequently went on to compete collapse and death, unless the fluid volume was restored and maintained. The benefits of saline infusions were often too transient to be dependable. Five per cent. glucose solution was of more service, but lacked the advantage of restoring the blood cellular loss, and had the disadvantage of causing occasional reactions.

A method of transfusion should be used that would give the fewest possible reactions. The direct method, using the Bernheim cannula, was most satisfactory, being practically free from danger and delivering the blood to the patient in its natural state. In the series reported whenever the blood transfusion was used in uncomplicated shock or hemorrhage the blood pressure was restored and recovery resulted.

In the seven cases reported, all patients below the average as operative risks. Four had carcinoma of the prostate and all of them some degree of arteriosclerosis. In two cases, transfusion was given because of hemorrhage, in two because of shock, and in three because of gradual failure of the circulation and inability to rebound. The four patients transfused for hemorrhage and shock were immediately relieved of their distressing symptoms and made uneventful recoveries. Of the three other patients, one recovered and two died. The one who recovered showed no distressing symptoms, except a gradual lowering of blood pressure and feeling of weakness. He was transfused thirty-six hours after operation, when his blood pressure had fallen to 88/58. He showed immediate improvement and made an uneventful recovery. The two patients who died were both operated upon for carcinoma of the prostate. One of these patients did well for twelve hours when his pulse rate began to increase and his blood pressure gradually to fall. There was also a rise in temperature and he was greatly distressed by persistent hiccough, vomiting, and distention. He was transfused twenty-four hours after operation with apparent temporary benefit, but died thirty-six hours later. The other showed considerable degree of shock three hours after operation, which was relieved by the intravenous administration of five per cent. glucose solution. Marked distention developed and the patient vomited and hiccoughed continuously. Five days after operation he was again given five per cent. glucose intravenously because of his inability to take fluids by other means. This was discontinued because of a chill after 200 c.c. had been given. A direct transfusion of eight minutes was then given with the hope of boosting him up, but there was no improvement and he died twelve hours later. The author summed up by saying that he believed transfusion was of great benefit as a general tonic to the anemic, debilitated, old man during his preparation for prostatectomy, and in the treatment of shock, hemorrhage, and the general asthenic state following prostatectomy.

Autonephrectomy.—Dr. Lionel P. Player, of San Francisco, Calif., presented a review of the literature of autonephrectomy with a report of experimental studies on rabbits and dogs in an endeavor to produce lesions similar to those encountered in humans by the blood, lymph and direct ascending routes, employing cultures of tubercle bacilli and pyogenic bacteria. He demonstrated a new method of diagnosis and reported an unusual case with patent ureter and pelvis with medullary and central portion entirely separated and walled off.

Urological and Clinical Diagnosis.—Dr. P. A. Rohrer, of Seattle, Wash., presented a statistical report of three hundred cystoscopic examinations. The important facts brought out were:

1. A negative uranalysis and a negative plain x ray plate did not insure negative kidneys.
2. The importance of urological study in helping to explain obscure abdominal symptoms.
3. The importance of urological examination as an aid to differential diagnosis in patients complaining of rightsided abdominal pain..
4. Mention was made of the number of genitourinary diagnoses confirmed by operation; also the abdominal diagnoses confirmed by operation.

Carcinoma of the Bladder.—Dr. J. Dellinger Barney, of Boston, reported an unusual case of carcinoma of the bladder. Hematuria occurred in a woman about fifty years of age, following hysterectomy for suspected carcinoma of the uterus, but in which no evidence of carcinoma could be found. Hematuria probably existed before hysterectomy was done. Several examinations of the bladder showed nothing whatever to cause blood and both kidneys were found to be negative. Finally, under the air bubble at the top of the bladder, a fine, hairlike stream of blood was seen to be pouring out, but no evidence of neoplasm could be seen. The bleeding was intermittent. After some months a tiny elevation the size of a blackheaded pin was seen at the point of hematuria. Believing that this was a papilloma, it was fulgurated on two occasions, with the high frequency current. After this no hematuria occurred for some time. Subsequently hematuria reappeared and the growth was seen as before and about the same size. Believing that an exploration should be made, operation was performed and re-

We herewith call your attention to a few of our pharmaceutical specialties. All these drugs are manufactured in accordance with detailed information given us by the originators, Knoll & Co., and are tested and accepted by them as equal to their well-established standard.

Bromural
a-monobromisovaleryl-urea.

A nerve sedative and mild hypnotic. Non-habit forming, not depressing, and well-tolerated. Induces refreshing sleep.

In 5 grain tablets and powder.

Ago-cholan
strontium cholo-salicylate.

A biliary stimulant and antiseptic, in biliary stasis and resultant disorders, hepatic insufficiency, and for the prevention of gallstones.

In 2 grain sugar-coated tablets.

Tannalbin
tannin-proteinate, exsiccated.

Well-tolerated intestinal astringent in diarrheal disturbances of various origin.

In 5 grain tablets and powder.

Diuretin
sodium-theobromine derivative.

A potent diuretic, vasodilator and cardiac tonic. Indicated in dropsy, arteriosclerosis, angina pectoris and cardiac asthma. Also used with digitalis.

In 8 grain tablets and powder.

Euresol
aceto-resorcin.

A stimulant and antiseptic for the skin and scalp. Applied in 2 to 5 per cent alcoholic solution in dandruff, falling hair, and itching scalp. In stronger ointments in skin diseases.

Ichthalbin
ichthyol-albuminate.

An intestinal astringent. For use in chronic intestinal catarrh and putrefactive processes.

In 5 grain tablets and powder.

SPECIFY *"Knoll"* IN YOUR PRESCRIPTIONS
and assure your patient a standardized and reliable drug

E. BILHUBER, Inc., 25 West Broadway, NEW YORK, N. Y.

vealed a hard, scirrhous type of carcinoma, involving the dome of the bladder on its peritoneal surface and extending laterally well down onto either side, especially the right. A transperitoneal resection of the bladder was done, removing all but a small cup containing the ureters and urethral orifice. Peritoneum was closed with drainage and the remaining portion of bladder sutured together around a rubber tube. Convalescence was stormy, but eventually the patient left the hospital in good condition. She has been seen since, several times; bladder function is entirely normal and there is no evidence thus far of recurrence. The report of the pathologist showed the typical appearances of carcinoma.

Fifty Years of Progress in the Treatment of Gonorrhea.—Dr. Victor G. Vecki, of San Francisco, Calif., presented an interesting summary of the advancement which had been made in the treatment of gonorrhea during the past fifty years. The following points were emphasized:

Until about fifty years ago practically only internal treatment was used; Sigmund's syringe was one of the first attempts at local treatment; the discovery of the offending germs; the centres of genitourinary activities; the use of suppositories; irrigations; the massaging of the prostate; instillations; vaccines; fuchsin and other dyes; local use of heat; intravenous medication; the pendulum swinging again the other way, towards internal medication.

Lowered Fertility in the Male.—Dr. Donald Macomber, of Boston, Mass., said that his paper did not deal with absolute sterility but with the recognition and treatment of conditions which reduced fertility in the human male. Fertility was a variable quantity and might be affected by diet, climate, muscular tone, nervous energy, as well as by mild congestions or infections in the genital tract. Once fertile, always fertile, is a patent misstatement of fact. The methods of history taking and examination which aid in the recognition of these functional disorders were detailed—particularly those dealing with sex habits and the special examinations of the semen. The abstracts of several typical case histories were given to illustrate the various aspects of diagnosis and treatment.

A Device for Controlling Hemorrhage After Prostatectomy.—Dr. Edgar G. Ballenger and Dr. Omar F. Elder, of Atlanta, Ga., presented a lantern slide demonstration of a device for controlling hemorrhage after prostatectomy which differed from the usual hemostatic bags in that it could be introduced through the urethra like an ordinary catheter. This, they said, was of particular advantage when unexpected postoperative hemorrhage occurred.

The bag is introduced into the bladder through the urethra and is then distended with fifty to sixty c. c. of blue sterile salt solution. Traction is applied either by an attendant or by light weights (one or two pounds) as required. Being distended with a blue solution enables the nurse to recognize at once any leakage from the bag in case it is damaged during or after its introduction.

The small size and great strength of these bags are made possible by the use of the socalled fish skin condoms. This material is soft, thin and strong and is well adapted for such a purpose. There is one disadvantage, however, and that is that there are small holes in it, so it is necessary to use thin rubber under it, such as a finger cot or a Kollmann dilator cover to prevent the fluid from leaking.

Cylindrical sections of these two materials are smoothly tied around the end of a catheter and then a Kollmann dilator cover is passed over the bag to hold it smooth and even. When collapsed they are about 26 French. Small needle holes are made in the fish skin material to allow the escape of the fluid in case the inner rubber bag should break. Care must be taken in making these bags to see that the lumen of the catheter is not obliterated by undue tightness of the string which is placed around the bag to tie it to the catheter.

Impacted Calculi of the Ureter, Their Treatment and Result.—Dr. Alexander Hamilton Peacock, of Seattle, Wash., discussed the theory of the primary cause of calculi forming in the kidney and then wandering or descending the ureter. He said that the subsequent events depended upon the shape, size, elasticity, or the obstruction of the ureter from inflammatory tissue, stricture, or tumors. Naturally much depended upon the pathology of the ureter. Impacted calculi, namely, those which almost completely blocked the ureter and refused to pass a given point in seventy-two hours were those which the author considered in his communication.

The treatment consisted of meatotomy of the urethral opening, with dilatation of the ureter, injections of oil, or a ureterolithotomy. Rough, impacted calculi produced very definite trauma and often permanent injury to the ureter. Strictures resulted, infection of the kidney might take place, and nephrectomy might become necessary.

The pertinent point of the paper was: What constituted the best method of relieving impacted ureteral calculi?

Present Status of Hexylresorcinol as an Internal Urinary Disinfectant.—Dr. Veader Leonard and Dr. Austin Wood, of Baltimore, Md., presented a report of the clinical results obtained from the use of this drug, with illustrative cases classified on an etiological basis. The following points were discussed:

Experimental background and rationale of hexylresorcinol as an internal urinary disinfectant; experimental and clinical evidence of the superiority of olive oil solutions over other forms of administration, further observations on the mechanism of the bactericidal action of hexylresorcinol in the urinary tract; the significance of variations in the surface tension of the urine in relation to the interfering action of certain therapeutic measures commonly employed.

Bladder Reflux.—Dr. Daniel N. Eisendrath, of Chicago, presented the following summary and conclusions to an experimental and clinical study of bladder reflux:

1. By bladder reflux is to be understood the regurgitation backflow of bladder contents into the ureters and renal pelves.

2. The condition may be congenital or develop in postnatal life. That it is not a permanent affection is shown by the first case reported, where a marked reflux complicating atony of the bladder and

Exclusive Manufacturers of Sponge Rubber Pad Trusses Since 1906

due to spinal syphilis, entirely disappeared after appropriate local and general treatment.

3. Reflux plays an important part in carrying the infection from the lower to the upper urinary tract and explains the recurrence and resistance to treatment in such cases.

4. It may lead to an erroneous diagnosis of bilateral renal tuberculosis because it is a frequent complication of that disease.

5. It is extremely rare in normal individuals and during pregnancy. Acute and chronic cystitis favor it because of changes in the lower ureter preventing proper closure of the orifice on one or both sides.

6. In 91 cases including normals, pregnancies, and various vesical and renal conditions, reflux was only found in 5 or 5.4 per cent., most frequently in infections of the bladder and kidney, both tuberculous and nontuberculous. Obstruction at the vesical neck is a comparatively rare cause of reflux.

7. There is still much difference of opinion as to the reason why the mechanism at the ureterovesical junction, which normally opposes the reflux of bladder contents, should fail to function. Some hold that a hypertonic vesical musculature forces the ureteral orifices open. Some believe that a congenital insufficiency will explain all cases. A third group hold that changes in the wall of the lowermost portion of the ureter from lack of innervation or disease prevent the proper closure of the orifices. One must concede that all three of these may coexist, or even acting alone be sufficient cause for the phenomenon.

SECTION ON ORTHOPEDIC SURGERY

CHAIRMAN, DR. F. J. GAENSLEN, OF MILWAUKEE.
SECRETARY, DR. JAMES ARCHER O'REILLY, OF ST. LOUIS.

Birth Injuries Requiring Orthopedic Treatment.—Dr. Samuel W. Boorstein, of New York, said that by birth injuries he referred to traumatic injuries sustained during labor and delivery and in the common and necessary manipulation of the newborn. He emphasized the point that injuries sustained at birth often remained undiagnosed and thus the opportunity for treating at the most advisable time was lost. Hence he urged that the attending physician acquaint himself with the early symptomatology with the view of resorting to early orthopedic treatments when required. He discussed the following birth injuries: obstetrical brachial paralysis, fracture of femur, humerus, spine and cranium, torticollis and intracranial injuries. In the etiology of intracranial lesions he considered the trauma sustained at the delivery as the main cause. The early symptoms, he said, by which the spastic cases could be recognized were: The infants were restless and cried almost incessantly. Pressure upon the fontanelles produced respiratory distress, screaming or even convulsions. If the hemorrhage was not excessive, these infants refused to nurse. Nursing usually was poor and clumsy. Retinal hemorrhages, inequality of the pupils, squinting and nystagmus were often found.

For orthopedic prophylactic treatment he advised very early attention to the prevention of deformities, hence believed that the infants should be put in a double Thomas abduction frame with attachments to keep the shoulders abducted and rotated outward and provisions for increasing the abduction of the lower extremities, the feet at right angle, the elbow slightly flexed and wrist hyperextended on a splint.

In obstetrical brachial paralysis the author gave the following conclusions:

1. Obstetrical brachial paralysis was due to stretching or tearing of the cervical roots of the brachial plexus.

2. It was almost always associated with a difficult labor; in many instances, forceps having been used.

3. If these cases were treated early and properly, one might expect in the mild cases a good recovery in three or four months.

4. The more severe cases would require about six or seven months for a complete recovery.

5. Nerve operations were indicated if no advance was made in four months. After that period, if sufficient improvement was noticed, one might wait four months more, provided, of course, proper orthopedic treatments were continued.

6. The shoulder should immediately be put up in a splint or brace to prevent stretching of the paralyzed muscles and contracture of the unopposed muscles.

7. Even in the whole or the lower type, one might try conservative treatments for a while and then resort to a plexus operation. The result was not so discouraging as some textbooks would lead us to believe.

For fractures of the femur and humerus a Thomas Jones' splint, preferably with a half ring, should be used. The advantages were: It allowed easier transportation, permitted cleansing of the children and saved a great deal of watching. It permitted early massage. The deformity was easily controlled. The union probably occurred earlier on account of the ability of the infant to use the limb, to elevate it together with the brace. For fracture of clavicle a figure of eight bandage should be used; for fracture of vertebral column a Bradford frame. In reference to torticollis the author said that many of the cases might be caused by hematoma of sternocleido mastoid at birth. For treatments he puts up in a felt collar.

Dr. Boorstein's general conclusions were:

1. Many permanent injuries were traced to parturitional trauma.

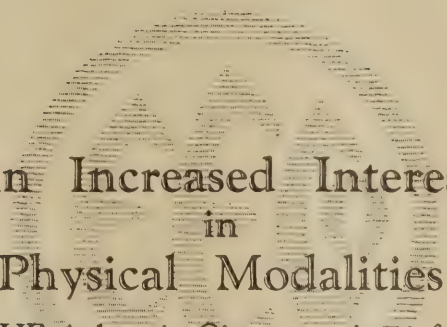
2. Many of these injuries could be diagnosed at birth if careful examination was made.

3. The obstetrician or the general practitioner should acquaint himself with the proper methods of prompt diagnosis so that early treatment could be instituted where necessary. If he himself could not diagnose the case, he should consult the orthopedic surgeon.

4. The spastic cases should be treated at once even when there was doubt that the mental condition of the child would ever be normal; one could not foretell how much mental recovery would be obtained.

5. The armamentarium of obstetrical service in the hospital should include the braces or wire splints necessary for immediate attention in these cases.

6. Cases of intracranial injury were treated by a double Thomas abduction frame with arm attachments.



An Increased Interest in Physical Modalities

THE Atlantic City meeting of The American Medical Association indicated a marked increase in the use of Physiotherapeutic methods. The papers presented at the meeting showed that the many ethical modalities which this branch of Therapy includes are opening up new methods of Medical Endeavor very rapidly Because the Engeln line of Diatherm and X-Ray Equipment was accorded so much attention we felt that a great many Physicians would be interested in seeing some of the new literature which describes this equipment, as well as reprints of articles which have appeared in some of the well known Medical Journals. These reprints together with our new publication "The Modern Science of Diathermy," will be gladly sent at your request.

The Engeln Electric Co.

X-Ray and Physiotherapy Equipment

CLEVELAND, OHIO

7. Obstetrical brachial paralysis was best treated by a plaster or an abduction splint keeping the arm in abduction and outward rotation. Later on massage and exercises should be instituted.

8. Fractures of femur and humerus should be treated with a small splint.

9. In fractures of the spine the patient should be kept on a Bradford frame.

10. Torticollis was prevented by a felt collar around the neck.

Neuroarthropathies of Peripheral Nerve Injury Origin.—Dr. Herman B. Philips, of New York, and Dr. Charles Rosenheck, of New York, presented a paper on this subject with a report of two cases and a lantern slide demonstration. They said that the condition was a new clinical entity, the two cases which they reported presenting striking similarity in histories, symptoms, laboratory findings and course. It developed, insidiously, after a severe local injury, in a person subjected to severe and oft repeated muscular strain. Diagnosis was made by the recognition of a combination of both physical and x ray findings of a neurotrophic joint with negative neurological and serological data, with a history of delayed onset after an injury. Marked swelling of the joint was present with distention of the synovial and bursal sacs. There was marked disintegration of the joint with destruction of the articular ends of the bones. Pain was absent or present to a slight degree not commensurate with the amount of destruction. In other words, the joints presented typical characteristics of Charcot disease or syringomyelia without confirmatory neurological or serological findings. The absence of the classical neurological and serological findings, in both cases, led to faulty diagnosis and treatment prior to our observation of the cases, and in one patient the shoulder was operated upon for supposed sarcoma.

These neuroarthropathies of peripheral nerve injury origin had a startlingly high incidence, occurring in two out of twenty-five consecutively observed cases of neurotrophic arthropathies observed by the authors. The incidence of this condition is twice as great as that caused by syringomyelia, there being but one case of the latter disease in their series. The authors believed that the unusual combination present in this clinical concept must be stressed so that the condition could be recognized and faulty treatment avoided.

Resection of Long Bones for Chronic Osteomyelitis.—Dr. George I. Bauman, of Cleveland, Ohio, presented a report of partial or complete resection of twenty-eight long bones in twenty-three patients suffering from chronic osteomyelitis. In this series there were resections of the femur, tibia, fibula, humerus, ulna and clavicle. The author discussed the possibility of regeneration after resection of the shaft in these various bones, and demonstrated special technic of operation and aftercare, with lantern slides showing the various stages of regeneration.

Mechanics of Back Strain.—Dr. Z. B. Adams, of Boston, Mass., read a paper on this subject in which he emphasized the following points:

1. An explanation of the type of cases considered.

2. An analysis of the motions permitted at the various levels of the spine.

3. A description of the structures which normally limited the direction and extent of these motions.

4. A description of two anatomical specimens which illustrated what happened when this mechanism was defective.

5. Suggestions as to what the treatment of this condition should be from the anatomical conditions which caused it.

Reconstruction and Plastic Operations of the Hip.—Dr. Fred H. Albee, of New York, said that in no other joint were the possibilities of reconstruction and plastic surgery greater than in the hip; yet, owing to the peculiar anatomy of this deepseated ball and socket joint with the most powerful muscles of the body acting upon it, such operations had only been attempted within the last decade. Modern additions to the surgeon's armamentarium, including the Smith-Petersen incision for approach to the joint, the Albee orthopedic fracture table and bone mill, and the introduction of bone grafts from one part of the anatomy to another, had so far widened the field that at present the limits were only set by the ingenuity and experience of the operating surgeon.

Two groups of cases were discussed; those in which operation aimed to maintain mobility, and those in which arthrodesis was desired. In the first group, ununited fractures of the neck of the femur, and congenital and acquired dislocations were included; also a rather unusual case of old arthroplasty for mobility of the hip, with subsequent dislocation was reported. The relative merits of the bonegraft peg and the Albee reconstruction operation were considered. In the author's opinion, the latter was preferable in ninety per cent. of cases. It offered a shorter convalescence, which was an advantage, especially in older patients. Moreover, if there had been extensive erosion of the bone, with loss of a considerable portion of the neck of the femur, and if the head was shortened, even though the bone graft operation might be technically successful, the anatomy of the parts had suffered to such an extent that range of motion at the hip, and the efficacy of the graft were necessarily impaired. The bone-muscle lever formed by the author's reconstruction operation more closely simulated the normal physiological lever than any device so far reported. The technic was given in detail, and also an illustrative case.

In cases of congenital or acquired dislocation in which the acetabulum was so shallow, or the head so faulty in shape that the head would not remain in place after reduction; and in cases in which the leg had been so shortened and the hip so far elevated that it was impossible to deliver the head into the acetabulum, it was necessary to construct an acetabulum higher up on the ilium, by means of bone graft wedges, by reshaping the roof of the acetabulum, etc.

Review of a series of seventy-five cases in which the author had produced arthrodesis of the hip led him to the conclusion that no joint in the body was better adapted to arthrodesis, or offered a better functional result. He had been performing such operations for various conditions, including arthritis deformans, tuberculosis in the adult, infectious arthritis, comminuted fractures, and paralytic conditions, for more than fifteen years, and was still surprised by the functional excellency of the late results. This group of cases afforded a very high percentage of thoroughly satisfied patients.

AMPOULES

[PARKE, DAVIS & COMPANY]

COMMEND THEMSELVES TO THE CAREFUL PHYSICIAN

Because

(1) In them the element of chance is superseded by the certainty of science.

(2) They are ready to use and easy to carry. No time is lost in making up solutions as required.

(3) They are made with full consideration of the characteristics of every ingredient. The glass employed is one which will not react with the solutions contained in them.

◆

AMPOULES PRESENT AVERAGE SINGLE DOSES OF IMPORTANT DRUGS

readily transferable to the hypodermic syringe, and less likely than improvised solutions to irritate the subcutaneous tissues.

The principle of standardization, which has given character to our products as a whole, is rigorously applied to the ampoule list, comprising a wide variety of formulae.

Of the line offered by Parke, Davis & Co., some are especially intended for intravenous use although, with very few exceptions, any solution in the list can be thus administered, the only desideratum being that which the physician alone can supply, namely, intravenous technique.

Our 48-page, therapeutically indexed booklet on Ampoules is sent to interested physicians on request.

PARKE, DAVIS & COMPANY

DETROIT ~ MICHIGAN

The author first introduced the operation for arthrodesis of the hip at Budapest in 1909. Since then, in order to obviate delayed union, he had modified the original technic. The modified technic was described in detail. Three patients who suffered from adduction flexion deformity, with acute symptoms, and who had been treated by manipulation quite unsuccessfully, had obtained satisfactory results from arthrodesis.

Attenuated Bone Infections. Considerations in the Treatment of Osteomyelitis.—Dr. Walter M. Brickner, of New York, said that the phenomenon of attentuation and longevity in the bones of pyogenic bacteria was exquisitely illustrated in the chronic bone abscess, and was to be observed in other latent local and metastatic foci of osteomyelitis. In these conditions, especially, it afforded opportunities for conservative surgery—drill drainage of chronic bone abscesses, incision of subperiosteal abscesses, simple sequestrectomy, etc. The important pathological process in chronic osteomyelitis was bone necrosis. There was a definite causal relationship between this necrosis and suppuration. When all the necrosed bone escaped or was removed the suppuration usually ceased.

He believed that two important principles applied in the surgery of chronic osteomyelitis: First, the bone itself should not be attacked until a sequestrum had definitely formed; second, the simple removal of sequestra might be all that was necessary to effect healing, in spite of overhanging healthy bone. As a rule, sequestrectomy only should serve as a primary operation. The shallow bone trough might be required to effect definitive healing, but plastic osteotomy might be wisely deferred until its necessity and extent were definitely indicated.

Osteotomy could not be applied in all situations to eradicate bone cavities, which, however, sometimes closed up or closed over spontaneously. For an indolent cavity surrounded by a wall of dense bone Brickner suggested the drilling of small holes through that wall. In acute osteomyelitis extensive gutter osteotomy was not necessary, and scraping out the cancellous bone was to be severely condemned. Drainage could be provided through drill holes (trephinage) of sufficient size and number, or through bipolar trephinage; and suppurating medullaris may be adequately evacuated with gauze or irrigation.

Chronic bone abscesses might be medullary or cortical, he said, and at any level of the bone, and were rarely tuberculous; their symptoms were pain and bone tenderness, occasionally slight fever. He explained in detail how to recognize chronic medullary abscess. Chronic bone abscesses were usually residual from, and gave symptoms years after, acute osteomyelitis. Brickner illustrated, however, a series of solitary, chronic, sterile, cortical abscesses of the femur without any discovered antecedent infection. Chronic bone abscesses were usually sterile or nearly so. Osteotomy was therefore not necessary for their cure, in the author's experience. His method of treatment by simple evacuation through a small drill hole had been uniformly successful even in his nonsterile cases. The author's technic, which had previously been published, was again described in some detail.

Diathermy in Joint Injuries.—F. H. Ewerhardt, of St. Louis, discussed first the more generally known forms of heat, conductive, convective, and conversive. Conduction, he said, was that form of heat which was conveyed to the body by virtue of direct contact with a superheated substance. Convective heat radiated from a source approximating, but not in contact with, the body. The numerous so-called bakers, whether heated by gas burners, or electrical resistance wires of electric light, were forms of convective heat. With respect to the latter a qualifying statement was essential. Light from the viewpoint of heat producing agency, operated in two distinct and definite ways, which placed it in two of the three groups. That part of the heat which was generated as a result of meeting resistance in its passage through the glass bulb and the air intervening between the source and the part to be radiated, was distinctly a form of convective heat, while the remaining rays, visible and invisible striking the skin penetrated it, and meeting increased resistance were in turn converted into heat, thus forming and belonging to a third type, namely, conversive heat. This form might be defined as one in which light or electric energy, in its passage through human tissue was converted into heat. By the term diathermy was meant the process of heating through the tissues as contrasted with convective and conductive heat. The source of diathermy was a high frequency current of high voltage and relatively low amperage. The strength of the current used might be any part from one hundred to three thousand milliamperes. The extreme high rate of alterations or oscillations might range from one half to two million a second and were so far removed beyond the point where human tissue responded either by muscular contraction or electrolysis, that the result was a conversion of the electric energy into heat energy. For these reasons it was not correct to speak of diathermy as being an electrical treatment *per se*.

The physiological effect of convective and conductive heat was a vasomotor dilatation followed by a venous stasis and frequently by free perspiration. The heat, however, penetrates barely beyond the dermis for here the abundant vascular system dissipated it to other parts of the body. Wherever a relaxation of the superficial tissues was desired, this form of heat was indicated.

The action of radiant light and heat for localized purposes was much the same as that of conductive heat with the difference that the light rays possessed a definite power of penetration, some deeper than others, and were then converted instantly into heat, and though a considerable quantity of it was carried off by the blood stream, yet much of the total volume was carried deeper into the tissues. Diathermy, the author repeated, was a means of heating deep tissues by means of a high frequency current which passed from one electrode to the other in straight lines affecting whatever tissue intervened. He believed that the method should appeal to the surgeon who believed in the efficacy of the functional treatment of fractures and joint injuries.

Ewerhardt's conclusions, based on an experience of two years in the physiotherapeutic department of the School of Medicine, Washington University, were as follows:

HANOVIA QUARTZ LAMPS

Alpine Sun Lamp Kromayer Lamp

ORIGINAL PIONEERS IN 1905

You cannot mistake a HANOVIA QUARTZ LAMP for any other. Those who take pride in their quartz lamps value this distinction. It is assembled by skilled workmen who have devoted years in the HANOVIA Plant to the creation of a fine mechanical work.

These features with the entire quartz mercury anode type of burners, which give the maximum intensity of Ultra Violet Rays, should be strongly considered.

"1. That diathermy is a safe heating procedure which can be localized in deepseated tissues at will; the degree of intensity may be satisfactorily regulated by means of suitable electrodes of varying sizes, properly applied and augmented by the cooperation of the patient.

"2. That it is a valuable measure at least a partial control of pain, spasm, and swelling in the earlier stages of fractures and joint injuries and contributes therefore, materially to a favorable functional end result.

"3. That patients take kindly to it, are favorably impressed with the procedure, and their cooperation is more easily secured where movements and massage are indicated.

"4. That unquestionably the period of convalescence in the treatment of fractures is materially reduced.

"5. That its application seems indicated in postoperative bone and joint conditions, acute sprains, fractures, and bursitis; acute and chronic arthritis, and in treating contractures, fibrositis, and myositis ossificans.

"6. It is contraindicated in cases of pus sac without drainage, where there is danger of hemorrhage, and in tuberculous joints and suspected malignancy."

SECTION ON SURGERY, GENERAL AND ABDOMINAL

CHAIRMAN, DR. EVARTS A. GRAHAM, OF ST. LOUIS.
SECRETARY, DR. J. TATE MASON, OF SEATTLE, WASH.

Diaphragmatic Hernia.—Dr. Carl A. Hedblom, of Madison, Wis., presented a review of 378 cases of diaphragmatic hernia in which the patients were operated upon. He summarized his findings as follows:

Nineteen of the cases were from the Mayo Clinic and 359 from the literature. Excluding those due to war injuries 60.1 per cent. were due to trauma, 14.7 per cent. were congenital, 14.8 per cent. were acquired, and 10.3 per cent. were of indeterminate origin.

Among the patients were twenty-two children under ten years of age. The duration of the symptoms in the traumatic cases was three years or under in about eighty per cent. while in those of congenital and acquired origin it was more than three years in fifty-four per cent. In a considerable proportion of the cases of traumatic origin there was a latent period between the injury and the onset of symptoms of hernia and in a large proportion months or years elapsed before operation.

The symptoms and signs in diaphragmatic hernia were variable. All the abdominal organs except those in the pelvis were a part of the hernia content in some cases. The stomach was herniated in 194 cases, the colon in 158, intestines in 56, spleen in 24. A sac was noted as present in 24. Of abdominal symptoms, pain, vomiting, constipation, and distention were most common; of those referred to the thorax, pain, dyspnea and dysphagia were the most frequent.

Tympany and dullness to percussion, heart displacement and splashing and gurgling in the thorax were the most constant physical findings. Not infrequently the physical findings were very few.

Diagnosis was made on clinical or x ray findings in 59.5 per cent., at operation in 30 per cent., postmortem in 6.3 per cent., and uncertain 4.1 per cent. The diagnosis was made late in the cases eventually recognized.

Laparotomy was performed in 40.3 per cent. thoracotomy in about 39.2 per cent., and some combination of laparotomy and thoracotomy in 20.4 per cent.

The hernia opening was centrally situated in 22.7 per cent., lateral in 29.6 per cent., posterior in 13.5 per cent., and at the esophageal hiatus in 20.2 per cent. and variously situated in the remaining cases. There were six cases, three in the Mayo clinic series, of parasternal hernia.

The hernia opening was sutured in 72.6 per cent. of 362 cases, reduced but not sutured in 11.8 per cent., could not be reduced in 9.6 per cent., and was found at necropsy in 5.8 per cent. The hernia was successfully repaired in 49 per cent. of 146 cases subjected to laparotomy and in 89.4 per cent. of 142 cases in which the thoracotomy approach was used.

Of the nineteen patients operated upon at the Mayo Clinic, fifteen recovered from operation, two with congenital absence of the left diaphragm died one and eight years after operation, respectively, one recurred but has been symptom free since the second operation. Twelve patients have remained free of symptoms of recurrence. Four, twenty-one per cent., died of shock, cyanosis, pulmonary embolus and sepsis, respectively.

Of the total number 251 patients (66.4 per cent.) recovered from operation, but in 42 of these cases no attempt was made to suture the hernia.

The operative mortality in 126 obstructed patients was 53.1 per cent.; in 252 who were nonobstructed it was 23.8 per cent.

The operative mortality excluding obstructed cases and those with omentum prolapsed through the chest wall was 22.3 per cent. following laparotomy, and 19.8 per cent. following thoracotomy.

End results were reported in a small percentage of cases. Of twenty-three patients in whom the opening was closed by suturing an adjacent organ into it, four were reported to have died later of intestinal obstruction and in four the hernia recurred.

The author drew the following conclusions:

1. The etiology of diaphragmatic hernia was often obscure, its pathological anatomy diversified and its clinical manifestations manifold.

2. About two thirds of the reported civilian operated cases in which the etiology could be assigned had been due to a penetrating wound or rupture of the diaphragm, by sudden greatly increased abdominal pressure, one sixth were congenital and one sixth acquired.

3. A large proportion of the reported operated cases were recognized only after symptoms had been present many years. A considerable proportion were unsuspected until discovered at operation, sometimes after a number of previous operations, and some were disclosed at necropsy.

4. The failure to make an early diagnosis was doubtless due in some measure to the variable and uncertain clinical manifestations but probably for the most part due to the fact that the condition was not considered in the differential diagnosis. The

"There is no doubt that menstruation depends on the functional activity of the ovary."

Human Physiology—Starling, 1920.

AMENORRHOEA
DYSMENORRHOEA
MENORRHAGIA

HORMOTONE
Hormotone presents hormone bearing extracts of the thyroid, pituitary, suprarenal, ovary and testis. Each tablet contains 1-10 gr. desiccated thyroid and 1-20 grain whole pituitary.
Hormotone is a logical combination of these dynamogenic hormones. The usual dose in adrenal insufficiency and asthenic conditions is 1 or 2 tablets before each meal, not more than 6 per day.
In high blood pressure use Hormotone without Post-Pituitary.
HORMOTONE
G.W. CARNRICK CO.
New York, N. Y.

are best controlled by internal secretion therapy which acts directly on the ovary and the endocrine glands associated with it.

HORMOTONE

is a combination of those glands which together determine and regulate menstruation—ovary, thyroid, pituitary and adrenals. It is usually successful in correcting these conditions.

Dose: 1 to 3 tablets three times daily.

G. W. CARNRICK CO.

417-421 Canal Street G.W. CARNRICK CO. New York, N. Y.

history of a penetrating wound of the lower thorax, of a crush, collision, or fall, or the presence of symptoms referable to the abdomen or thorax or both should suggest the possibility of diaphragmatic hernia in every case in which the diagnosis remains in doubt.

5. In the differential diagnosis chief reliance must be placed on the röntgen ray demonstration of an abdominal viscus in the thorax following administration of a meal or enema opaque to the röntgen ray. Failure to demonstrate the hernia röntgenologically might be due to spontaneous temporary reduction, to the failure of the opaque substance to enter the herniated viscus or to the presence of a solid viscus only, such as omentum, in the hernia.

6. In the absence of definite contraindications an exploratory operation should be performed if diaphragmatic hernia was suspected and following a positive diagnosis even if the symptoms were slight. In a large proportion of cases obstruction finally developed and that complication at operation more than doubled the postoperative mortality, limited what might be attempted in the way of repair of the hernia and often necessitated secondary operations.

7. The choice between laparotomy and thoracotomy, in the author's opinion, depended on the nature of the case. In obstructed cases in which the cause of the obstruction was in doubt, exploratory laparatomy was indicated. If the hernia opening had been demonstrated to be parasternal, laparotomy furnished the most direct and practical avenue of approach. In cases due to a recent wound with prolapse of omentum through it, thoracotomy was the most direct approach and might be combined with a transdiaphragmatic exploration for injury to abdominal viscera. In the ordinary nonobstructed cases thoracotomy had yielded a somewhat lower mortality than laparotomy and successful closure had been effected in a much larger proportion of the cases following thoracotomy than following laparotomy. A combined thoracolaparotomy might be necessary to effect reduction and closure but such combined operation had resulted in a very considerable increase in operative mortality.

8. In more than ninety per cent. of the cases in which operation had been performed, there was no sac. In such cases the objection to thoracotomy because of operative pneumothorax produced was largely obviated for the reason that an operative pneumothorax was produced also through the laparotomy wound, the moment the hernia was reduced. Furthermore, the presence of abdominal viscera in the pleural cavity for months or years, probably in most cases, resulted in compensatory changes that increased the normal limit of tolerance to open pneumothorax. In any case the objection to thoracotomy on the grounds of pneumothorax was largely obviated by the use of positive pressure intrapharyngeal insufflation anesthesia, which amply sufficed to maintain respiration and to reinflate the lung if it was still expansile.

9. If possible the hernia ring should be sutured. Obturation of the hernia opening with some abdominal viscus was a makeshift which had resulted in a relatively large number of known recurrences. Suturing the stomach to the abdominal wall had proved ineffective in preventing its prolapse and was of no avail in preventing herniation of other viscera.

10. A few cases of large or recurrent hernia openings had been successfully closed by fascia transplants or muscle plastics. Very large openings, including cases with absence of the diaphragm on the left side, possibly might be closed by a plastic operation following extraplural thoracoplasty of the lower thoracic wall by extensive rib resection done as a preliminary operation.

11. Regardless of whether a thoracotomy or a laparotomy had been performed, the air should be aspirated from the pleural cavity after it had been closed. Even if the collapsed lung would not re-expand the negative tension produced probably in most cases would increase the negative tension and so increase the respiratory capacity on the opposite side. Atmospheric tension exerted on the mediastinum from the side of the collapsed lung added to the increased intraabdominal pressure due to returning the herniated viscera and postoperative distention might reduce the respiratory capacity beyond the limit of safety.

12. Recurrences following repair of diaphragmatic hernia had been reported in about five per cent. of the cases. Most recurrences were probably due to incomplete closure or to tension on the suture line.

13. The operative mortality had been due in large measure to late operation in the presence of obstruction, to shock and to respiratory failure. Early operation before obstruction had occurred, measures to prevent shock and differential pressure anesthesia and precautions against postoperative respiratory embarrassment should, therefore, greatly reduce it.

14. Operation for diaphragmatic hernia, whether laparotomy or thoracotomy, usually involved the technical consideration and problems of pneumothorax.

Amebic Abscess of the Liver.—Dr. Alexius McGlannan, of Baltimore, Md., presented a paper on this subject, with report of a case complicated by subphrenic abscess. Amebic disease of the gastrointestinal tract, he said, was usually associated with tropical maladies, but was often found to originate in temperate zones. The ease and speed of travel made dissemination easy. The surgeon's interest was centred on the complications and sequelæ of intestinal amebiasis rather than on the primary disease. The specific action of emetine on the Ameba histolytica had reduced the need for appendectomy and ileostomy.

Liver abscess was the most common sequel of the bowel disease. The pathogenic ameba had been found in the skin, in chronic bone lesions and other remote localities. The possibility of ameba causing gastric and duodenal ulcers was suggested.

Both the portal vessels and the transperitoneal route were given as the means by which the ameba traveled from the bowel to the liver. Amebic hepatitis and abscess were considered with regard to symptoms and emetine therapy and the importance of recognizing amebæ in the contents of an abscess. The author described treatment by means of open and closed drainage and the local constitutional use of amebicidal drugs.

He spoke of the complications of liver abscess, and the rarity of subphrenic as compared with intrathoracic abscesses. In commenting on the case reported, he referred especially to the usefulness of emetine in the successful treatment of this condition.

KALAK WATER

Carbonated

The Strongest Alkaline Water of Commerce

(Non-laxative)

A rational and rapid method of producing and sustaining the normal alkalinity of the body without systemic disturbance:

KALAK is prepared of distilled water and chemicals of reagent purity; is non-laxative and higher in available alkali and richer in calcium than any natural or artificial water known. The bases in one liter will neutralize 610 cc. of a standard tenth-normal hydrochloric acid solution.

KALAK expresses advanced alkaline therapy and replaces in modern and agreeable fashion the uncertain and often unwelcome methods of dehydration and alkalinization so commonly employed.

Each liter (approximately one bottle) contains in addition to 1.0927 grams of Disodium Hydrogen Phosphate and the natural salts of Sodium and Potassium Chloride, a total of 7.2978 grams of the Bicarbonates of Calcium, Magnesium, Sodium and Potassium, in physiological proportion so that their absorption is as rapid and complete as possible.

Kalak Water Company of New York

6 Church Street, New York City, N. Y.

SECTION ON GASTROENTEROLOGY AND PROCTOLOGY

CHAIRMAN, DR. RALPH W. JACKSON, OF FALL RIVER, MASS.

SECRETARY, DR. FRANK SMITHIES, OF CHICAGO.

The Correlation of Proctology with Other Specialties.—Dr. Ralph W. Jackson, of Fall River, Mass., in his chairman's address, said that proctology, as a specialty, had many independent problems, and was as often correlated with other specialties as with gastroenterology. Irregular more than regular practitioners had recognized this, and made profitable use of it. A society devoted to proctology alone had done much to advance the specialty, and the American Medical Association had recognized its legitimacy in a section including it, but should go further. The relation of anorectal work to other lines of specialization was brought about through anatomical proximity, blood and lymph channels, and neural connections. Through these, proctology was often correlated with gynecology, urology, pediatrics, orthopedics, dermatology, neurology and tuberculosis. These correlations made proctology as important a field of work as stomatology, which had a section of its own. Proctological papers on the programs of the Section on Gastroenterology and Proctology had been too few. More papers and their publication would foster the ethical growth of the specialty.

Stool Examinations for Protozoa in Inmates of a New York State Institution.—Dr. Walter S. Thomas and Dr. E. A. Baumgartner, of Clifton Springs, N. Y., reported that in a single examination of stools from 1,122 inmates of a New York State school for feebleminded women protozoa were found in 499 cases, or 44.4 per cent. Amebæ were encountered in 36.3 per cent., and flagellates in 23.7 per cent. Ciliates were not seen. Of the amebæ the entameba coli and endolimax nana were found in 17.8 per cent. and 17.7 per cent., respectively, while the entameba histolytica were present in only 1.07 per cent. Of the flagellates the chilomastix mesnili was seen oftenest, in 21.0 per cent., the giardia lamblia in 2.4 per cent., while the trichomonas hominis was seen only three times or in 0.26 per cent. of the cases.

That there was cross infection in the institution was shown by the relatively low incidence in the recent arrivals with a steady rise during the first year of residence after which the curve became flat.

The protozoon most often seen was the chilomastix mesnili; this differed from the figures of other observers and was explained by the fact that the stools with few exceptions were examined very shortly after they were passed, the organisms were still motile and therefore easily recognized.

The authors considered the most important findings to be the low percentage of entameba histolytica. Since this low rate occurred in a class of patients where the highest rate might be expected, in an institution where cross infection was evident, and since in none of the cases were there symptoms of amebic infection they concluded that in residents of New York State the entameba histolytica was an insignificant factor in the causation of disease.

Hydrogen Ion Concentration of Stools; Its Estimation and Clinical Value.—Dr. William H. Foreman, Dr. Walter E. Pennington, and Dr. Arthur G. Funkhouser, of Indianapolis, Ind., presented a comprehensive paper on this subject in which they stated that hydrogen ion concentration gave a more definite index of stool acidity than did any method of titration. This might be rather simply determined by the calorimetric method described by Nelson and Wilson in 1917, but using indicators not excessively sensitive to protein. The pH of the stool varied with the type of stool, ranging from above seven in the formed, solid stool to near five in the soft and liquid types. The pH of the stool influenced the pH of the urine and in diarrheas, reduced the Co_2 combining power of the blood.

The pH of the stool was modified by the character and reaction of colon wastes. The colon wastes were determined by: a, the chemical reduction and absorption of food, and rate of food and waste passage; b, continued enzmatic action and absorption in the proximal colon; c, the maintenance of a solid residue in the remainder of the colon. This necessitated a careful study of disease, chemical stimulation; the intestinal flora; fermentation and putrefaction; storage and elimination.

With the acid stool (pH 5.6-7.0), usually unformed, soft and agassy, the patient complained of digestive, systemic, nervous and psychic symptoms—a fairly definite but slightly varied syndrome. When by treatment the stool pH was reduced to neutral, the digestive, systemic and psychoneurotic symptoms are relieved, and the patients markedly improve in health.

Treatment was by dietary and digestive measures, the proper control of bowel wastes, and symptomatic treatment.

Lantern slides were used to demonstrate the principal points.

The Differential Diagnosis Between Cancer and Other Gastric Conditions Associated with Subacidity.—Dr. Seymour Basch, of New York, spoke of the importance and difficulty of making a correct early diagnosis of gastric cancer. The clinical conception of this disease, he said, included a diminution and subsequent disappearance of normal acidity and its later replacement by lactic and other organic acids. There was frequently confusion with pseudocancerous conditions, especially those associated with subacidity, and to aid in distinguishing between the subacid type of cancer and the subacid conditions, a brief discussion of the chief clinical manifestations of this type of gastric cancer was given. For the purposes of simpler discussion of the differential diagnosis, these last named were considered under two divisions: a, those associated with tumor formation, namely, sarcoma, benign tumors, tuberculosis and syphilis, and, b, those without tumor formation, namely, chronic gastritis, benign achylia and pernicious anemia. Detailed discussion of the differential diagnosis of each disease from gastric cancer.

The author's conclusions were:

1. Unless the presence of a cancer in the stomach had been positively established, the possibility of a noncancerous process should receive equal con-

WHEN ARGENTUM IS INDICATED

COLLENE

The Clean Silver

is non-irritating and non-escharotic

"IN POST-OPERATIVE CYSTITIS," a well-known surgeon says, "I formerly insisted on dilute silver nitrate solutions.

"Recently I have been instilling four ounces of COLLENE, after irrigating the bladder with a saline solution. The COLLENE is comfortably retained by the patient until the next urination, causing no distress whatsoever.

"During the past three or four years, I believe every one of my operative cases has had COLLENE instilled into the bladder. I should not care to return to the use of silver nitrate."

An important feature of COLLENE, not mentioned above, is that the silver content is not precipitated by "normal" saline solutions nor by urine. Samples of COLLENE containing 3.5% of sodium chloride—several times "normal" saline strength—were kept under observation for two months without any sign of precipitation or disturbance of the colloidal activity of the solution.

COLLENE is a stable silver solution, therefore constant in strength and action, and always ready for immediate use.

Liberal Samples and Literature Upon Request

THOS. LEEMING & CO., 130 WILLIAM ST., NEW YORK. M.J.

Gentlemen:

I wish to try COLLENE in

- ☐ cystitis
- ☐ nasal conditions
- ☐ eye work
- ☐ stomach ulcers
- ☐ colitis

You may send me without charge a supply of COLLENE suitably bottled for the work checked.

sideration. 2. Exploratory laparotomy was particularly urged whenever a careful study of a suspicious subacid case presented some feature which did not fit into the classical picture of gastric cancer. 3. This was particularly true in very early cases, for whether the process was cancerous or not, the patient's chance of recovery in surgical gastric affections was in direct proportion to the earliness of the operative procedure.

Some Reasons for Poor Results Following Gastrointestinal Surgery.—Dr. Russell S. Boles, of Philadelphia, said that the literature abounded with evidence showing that the results of operation for chronic appendicitis, gastroduodenal ulcer, and gallbladder disease were often disappointing. The reason operation failed to relieve symptoms was that the fundamental cause of the trouble had not been discovered. Isolated pathology in one organ of the gastrointestinal system rarely occurred. Focal infection and biliary and intestinal stasis paved the way for the development of chronic gastrointestinal disease. In addition, such constitutional abnormalities as a disordered sympathetic nervous system, neurasthenia, cecum mobile, gastroenteroptosis, redundant sigmoid, and familial predisposition, were important etiological factors. The management of these cases before and after operation reduced itself to four main essentials: 1, Eradication of the foci of infection, especially those of the teeth, tonsils, sinuses, upper respiratory tract, appendix, gallbladder, and colon; 2, elimination of intestinal stasis; 3, elimination of biliary stasis; 4, application of measures such as would improve the general condition of the patient.

In a large proportion of cases in which therapeutic biliary drainage was employed, decided benefit was secured. In cases of intestinal stasis, properly performed colonic irrigation had given striking alleviation of symptoms in the majority of cases. In ileal stasis, transduodenal lavage, by the Jutté method, afforded considerable relief. Diet was of paramount importance, one low in cholesterol being especially indicated in disease of the biliary tract. Only by such comprehensive management might recurrence of symptoms, reactivation or formation of ulcer, and recurrence of gallstones be avoided. Operation in all such cases must be looked upon as only an incident in the treatment of the patient. The pathological conditions mentioned were frequently merely an end result, and surgery alone could not be expected to effect a cure.

Therapeutic Value of Nonsurgical Drainage of the Biliary Tract.—Dr. B. B. Vincent Lyon and Dr. William A. Swalm, of Philadelphia, reviewed this method of treating disease of the gall tract, tracing its evolution from a diagnostic to a therapeutic procedure. They discussed the proper selection of cases of various types of the disease for surgical and nonsurgical management, pointing out the necessity in many cases of combining the two methods. The three vicious circles in gall tract disease were considered, the first responding to surgical procedures, the second and third to nonsurgical. Failure to recognize this led to postsurgical relapses and the necessity for reoperation.

The authors contrasted the value of intermittent with continuous nonsurgical drainage, and discussed very fully the present methods used, with observations on the physiology of the liver. In regard to the amount of bile secreted by the liver, the authors reviewed the results secured in 376 cases. The paper was well illustrated with lantern slides.

Subtotal Gastrectomy.—Dr. John B. Deaver, of Philadelphia, said that subtotal gastrectomy, formerly reserved for malignant disease of the stomach, was now much in favor for benign diseases, especially chronic gastric and duodenal ulcer and their sequelæ, such as, hourglass stomach, pyloric stenosis, secondary or marginal ulcer. The end results of the radical operation had proved so satisfactory in the hands of the author, that he now used the method whenever feasible.

The symptoms of gastric ulcer were not so well defined as those of the typical duodenal ulcer, so that diagnosis presented some difficulty. That the röntgenogram did not always demonstrate the presence of a gastric ulcer was illustrated by a recent experience.

In the case in point pylorospasm had caused pyloric obstruction as shown by x ray study. But the latter had failed to demonstrate the small ulcer which at operation was found on the lesser curvature of the stomach. Palpation of the pylorus at operation had even aroused the suspicion of a second ulcer, as the cause of the enlargement. But it was not found. A subtotal gastrectomy was done. Examination of the specimen showed three eighths of an inch thickening of the muscularis and submucosa of the pylorus.

Subtotal gastrectomy, Deaver believed, was the operation of choice for operable cancer of the stomach, which meant the early stage before metastasis had developed. A diagnosis or suspicion of cancer warranted exploration. Delay was dangerous, while exploration was not. If the latter failed to reveal the cancer, so much the better, but it would most likely reveal sufficient pathology to account for the symptoms, and its removal will afford a chance, and a very good one, for relief. A palpable gastric tumor did not necessarily mean inoperable cancer, especially if the growth was a small one located at the pyloric end of the stomach. Large growths at the cardiac end, of course, preclude gastric resection. Gastroenterostomy for cancer of the stomach served no purpose unless the pylorus was obstructed. When such was the case, it was a warranted measure provided the condition of the patient permitted.

Normal Gastric Digestion.—Dr. Martin E. Rehfuss, of Philadelphia, spoke on new conceptions regarding gastric function. He believed the stomach to be fundamentally the organ of food digestion. He discussed the theories of Meunier, Dodds, Bolton and others, regarding certain gastric phenomena, and gave a summary of a complete study of gastric digestion as performed in the department of physiological chemistry of Jefferson Medical College, with unpublished data completing the normal digestion table. He also presented secretory and motor tables of foodstuffs, and gave röntgenological and intubation evidence regarding normal, fast, and slow stomachs. He gave what he considered the probable explanation for intragastric phenomena as revealed by intubation, showing clearly three periods. These were studied in detail, as a basis for the interpretation of pathological data.

What "L & F" means on pharmaceuticals

CONFIDENCE

WHEN you specify "L & F" you can do so with implicit confidence in the purity of the remedial agents you prescribe.

In purity, accuracy and strength, all "L & F" pharmaceuticals meet, in the highest degree, the requirements of U. S. P. and N. F. standards.

IN ADDITION to being the makers of Pebeco Tooth Paste and the distributors of "Lysol" Disinfectant, we manufacture over 5,000 products in our model pharmaceutical plant at Bloomfield, N. J. We call your attention especially to the following "L & F" preparations:

Endocrine Preparations

Ovarian Substances, Pituitary and Thyroid in all the usual sizes. 24 hours from animal to finished product. Not cooked, but dried. Maximum temperature never over body heat. Time of drying is less than 4 hours which decreases bacterial decomposition.

Triophos

A neutral antacid. Removes only the free acid. Does not influence the acid-alkali balance of the blood.

Milk of Magnesia

Fluid Extract of Cascara

Aromatic and plain.

If you are not receiving our quarterly publication, "Notes on New Remedies and Medical Progress," we shall be glad to send it to you regularly upon request.

SECTION ON NEUROLOGY AND PSYCHIATRY

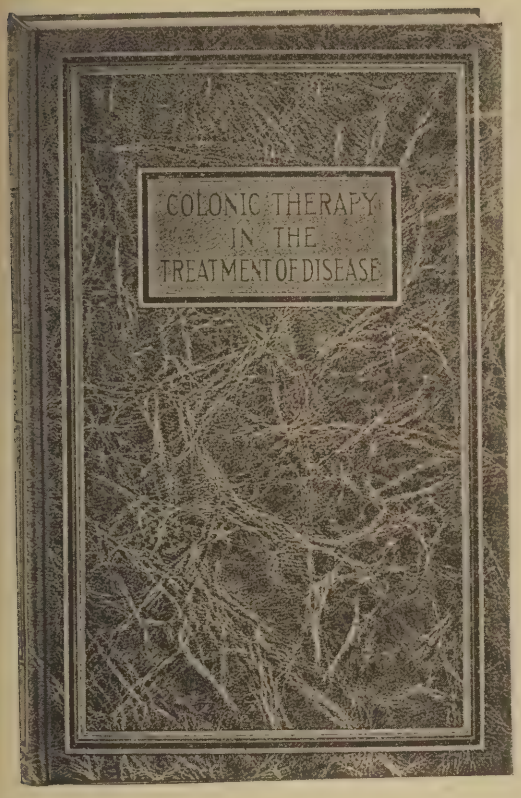
CHAIRMAN, DR. EDWIN G. ZABRISKIE, OF NEW YORK.
SECRETARY, DR. LEWIS J. POLLOCK, OF CHICAGO.

Meralgia Paresthetica; Its Relation to Osteoarthritis of the Spinal Vertebræ.—Dr. Charles Rosenheck, of New York, said that the former and present day conception that meralgia paresthetica was a peripheral nerve affection involving the external cutaneous nerve of the thigh must be abandoned. The vague causes that had been assigned, viz., trauma, infections, pregnancy, flat feet, and other ill defined states, as being responsible for the meralgic syndrome, must also be discarded. Since Roth and Bernhardt in independent contributions described the affection and stressed the rôle which the long course of the external cutaneous nerve and its relation to the fascia lata played in the causation of meralgia, every writer on the subject and every textbook had copied this glaring inconsistency. Neither the long course of the nerve or its exposed position or the other vague causes mentioned were the etiological factors concerned. In a series of twenty-five cases of meralgia paresthetica it had been proved that the affection was radicular in nature and its origin or etiology might be traced to inflammatory deposits in the intervertebral spaces. Osteoarthritis of the spinal vertebræ, particularly the lumbar segments, had been found in the series studied. This had been proved clinically and by röntgen ray.

Alteration of Character, Disposition and Behavior as a Sequela of Encephalitis Lethargica.—Dr. Alfred Gordon, of Philadelphia, said that encephalitis lethargica might be followed by a psychosis which could be considered as an akinetic expression in the psychic activities analogous to the akinesia in the motor sphere characteristic of the encephalitis. The condition might simulate a depressive psychosis or a demented state. Besides the purely psychotic phenomena analogous to those observed in the classical psychoses there was another set of manifestations observed especially in young persons, which had reference to alteration of disposition and of the personality in general. To demonstrate the latter the author reported in great detail the histories of seven cases all showing postencephalitic sequelæ in the domain of the emotional sphere. The author believed the outstanding features of the disorder to be: Aggressiveness, hostility, impulsiveness, outbursts of excitement or anger, restlessness, discontentment, tendency to misrepresent or frankly to lie without any specific motive, tendency to misappropriate or to steal, and excessive eroticism. This group of symptoms, which could be called psychomotor instability, had this characteristic feature that it did not occur periodically as had been observed in psychotic states, but it presented a continuous condition without intervallary periods similar to purely motor manifestations of lethargic encephalitis in which the symptoms existed for a long time without modifications. These symptoms might be individually encountered in some of the classical psychoses but collectively they could not be identified with the latter. They constituted a clinical entity apart, because they involved exclusively the domain of emotional forces but not the intellectual forces. The latter were invariably intact in every one of the cases reported. A careful mental examination failed to reveal any disturbance whatsoever in the association of ideas or of judgment. In all such cases one witnessed a distinct dissociation between the psychomotor instability and the integrity of the intellect. As to affectivity, it might at first glance appear to be involved so as to give the impression of a true psychosis in its early development but contrary to what was observed in the latter; in the postencephalitic cases the patients were very sensitive to the consequences of their deviations from the proper conduct, they expressed genuine regret and showed a state of anxiety and painful criticism of their behavior which was not voluntary, not thought out or deliberate; otherwise speaking, these manifestations were not the result of a fundamental mental disorder, they were but the expression of a morbid emotional state and the effect was here involved only in its reactions and in the power of execution but not in its central power.

The next point of interest emphasized by the author was the prognostic outlook of the personality disorder. The seven cases upon which the present study was based showed that the individuals whose previous personal and family histories presented psychotic phenomena, had an unusually long duration of their postencephalitic disturbances. On the other hand the patients whose antecedents were normal, made a complete recovery. It seemed, therefore, that the postencephalitic cases followed the same laws as hereditary influences from any source. The author expressed an opinion that these emotional manifestations might find their physiological explanation in the alteration of the basal ganglia which, according to many writers, were ordinarily concerned in emotional phenomena. It seemed that the behavior disturbances were organic in nature and were a counterpart of the motor disturbances following encephalitis. The accumulated observations pointed more and more to an organic rather than to a psychogenic conception of postencephalitic behavior phenomena.

Parkinsonian States.—Dr. George B. Hassin and Peter Bassoe, of Chicago, presented a clinicopathological study of two large groups—paralysis agitans proper and postencephalitic syndromes, which they considered as Parkinsonian states. A comparative study of four such cases, one of paralysis agitans and three of the postencephalitic variety, was undertaken with a view to determining whether the forgoing conditions were identical pathological entities and whether they possessed a definite localization. The study of the four cases showed that pathologic changes though present in all, were not alike, regardless of the fact that in three cases the duration of the illness was the same—three years. In one case, for instance, the substantia nigra was markedly involved; in two, slightly, while in that of paralysis agitans it was involved not more than any other portion of the central nervous system. This last case differed from the postencephalitic variety in the absence of inflammatory phenomena which in the postencephalitic cases were combined with diffuse degenerative changes. As the process was more or less diffuse, it was hardly possible to speak of a definite localization. It was certain, that the latter was not in the pyramidal system and that the extensity of the



It Is Every Physician's Duty to Investigate This Important Therapy

COLONIC THERAPY
in the Treatment of
DISEASE
BY SCHELLBERG

THE FIRST PRACTICAL BOOK ON COLONIC IRRIGATION

Based on twenty-five years of observation and experience, covers the subject from various aspects—scientific and practical. It embodies a discussion of the bacteriology and putrefactive processes of the alimentary canal in relation to colonic pathology as well as systemic infection. It emphasizes the importance of the Taeniae coli muscles in the mechanism of peristalsis, and reviews the mechanical and functional causes of constipation.

Gives in detail the technic of bacterial implantations—Bacillus acidophilus and Bacillus bulgaricus—discusses their merits and the value of antiseptic irrigating solutions, and—most important of all—describes and pictures the technic and instrumentation of colonic irrigation.

pathological changes might depend on the time element—the duration of the disease in each individual case.

Encephalitis Lethargica.—Dr. William Browning of Brooklyn, discussed a common etiological factor of encephalitis lethargica and its relation to prevention. He said that as neither the infecting organism nor the clinical causes had been established, accessory circumstances deserved study. His paper was based on twenty-seven private cases, twelve of which were a recent consecutive series. In these overwork and underrest proved to be a common causative element, most constant and demonstrable being loss of sleep. The normal sleep requirement varied slightly, but eight hours out of twenty-four was a minimal average standard. In the cases where this was calculated the amount obtained was less than seven hours in twenty-four, often much less. A single interruption of forty-four to forty-eight hours at a stretch could do the same thing. The difficulty was to ferret out the night habits of persons, usually impracticable in institutional and chronic cases. These nocturnes denied everything. The individual physician was more likely to be trusted with confidences. Many modern innovations tended to limit sleep, for instance, the radio, phonographs, automobiles, telephones, movies, crossword puzzles, changes in social customs, increase of studies and examinations, growth of urban life, and so on. Bad air, as in subways, and foolish talk against sleep add to the evil.

In line with this, a preliminary stage, lasting a month to a year or more, was not uncommon. This should permit recognition and relief of impending trouble. Knowledge of this factor proved useful in diagnosis. It neither negatived nor confirmed the theory of infection, but provided the soil or basis on which the disease developed.

Susceptibility proved to be due to excesses of this type, rather than to any great difference in immunity. Physicians for example, became affected, not from contact, but because of sleep interruptions and irregularities of living to which they were subjected.

Prophylaxis was largely a personal matter, except in some callings.

The Psychiatric Clinic in the General Hospital.—Dr. Irving J. Sands, of Brooklyn, N. Y., said that the purpose of the psychiatric clinic was to treat those mentally sick who did not require residence in a mental hospital, to manage the psychoneurotics, and the problem children, to guide the mental defectives, and to furnish information on general mental hygiene. Mentally sick people often refused to go to a psychopathic ward or hospital for treatment, but offered no objection to visit the dispensary attached to a general hospital. They always required a general physical survey and often a thorough serological study. Physicians were the first to whom the family turned for help. The range of the psychiatric knowledge of the general medical practitioner was limited. He was constantly in need of information on psychiatric subjects. During the past decade intelligent laymen had intense and increasing interest in mental hygiene, not only in its application to the problem of insanity but also to delinquency and criminology. Charity organizations, social service agencies, school authorities, and courts of justice were frequently seeking psychiatric advice in the management of their particular problems. When properly conducted, the psychiatric clinic in the general hospital would supply this want. Furthermore, by adequately treating the psychoneurotics and maladjusted, the clinic would prove an effectual weapon in combating the ever increasing numbers of quacks, illegal practitioners of medicine, and faddists.

Tonic Neck Reflexes in Tuberculous Meningitis.—Dr. I. S. Wechsler, of New York, discussed the clinical application of the tonic neck reflexes of Magnus and de Kleijn to tuberculous meningitis. He found the neck reflexes in a little less than half the number of cases in which he tried them and expressed the belief that they had some little clinical value.

Radical Cure of Neuroticism in Children.—Dr. Tom A. Williams, of Washington, D. C., said that the clinical evidence that neurotic manifestation could be permanently abolished in individual children was adduced in a number of papers in 1909, and was receiving the acquiescence not only of other clinicians, but the support of biological experimentation. Thus, zoologists and botanists had demonstrated that there was no fatality even about deeply rooted specific characteristics. They could determine by external causes the polarity of a germ cell and could alter its symmetry. They showed that the change of one structure altered the whole organism. Even a few hours' exposure to light, for example, of one part of an embryo would change the whole of it, even to the extent of the head taking the place of the tail. But even exuteral biological changes could be affected; thus, the transplanting of an ovary would cause the disappearance of male secondary characteristics already formed and the appearance of female characteristics. By modifying the diet in infancy, permanent changes of the individual could be induced, irrespective of heredity.

A universal alteration of every object to stimuli was not confined to those of mechanical or chemical nature, however, said the author. Dynamic stimuli were just as effective. Psychological experimentalists had proved that even the fundamental reflexes of pupil, gland and tendon could be modified. This could be done by adding to the sensation which aroused the reflex of other sensations simultaneously until gradually it was found that the latter became capable of arousing the reflexes without the former. This process was called association. By this means any stimulus might be made to arouse any response. It had long been known that every perception had its accompanying feeling tone, and that this latter manifested vasomotor changes and alterations in visceral states. The feeling tone aroused by any experience arose from only a small section of the whole experience. In virtue of this principle, devastating or inhibiting emotions became attached to what might appear to others to be simple everyday incidents, thereby producing a reactivity which was called neuroticism.

What could be conditioned in that way, he said, might be deconditioned or reconditioned in the

same way. The principle was easily comprehensible in a common fear, such as that of dogs, but it was no different when the fear appeared almost groundless. The phobia might wear an absurd garb, but within this was a real basis of dread which proper exploration of the patient's psyche would reveal.

The author cited examples of reconditioning through dynamic stimuli, through the bringing of a new element into the situation which had provoked the neurotic behavior. That element was a new feeling toward a conditioning on the part of the child gained by a newer perception of certain elements in the situation which had formerly perturbed him. In common language it was called understanding. The psychiatrist was a new element in the environment which permanently changed the patient in such a way that he responded differently to formerly hurtful surroundings. He had received light which changed him, just as light changed the formation of the experimental embryo. He had gained an immunizing power which enabled him to change hurtful elements of situations into helpful ones.

SECTION ON DISEASES OF CHILDREN.

CHAIRMAN, DR. EDGAR J. HUENEKENS, OF MINNEAPOLIS; SECRETARY, DR. HUGH MC CULLOCH, OF ST. LOUIS.

Neonatal Pyelitis.—Dr. L. W. Sauer, of Evanston, Ill., said that despite the wealth of contributions on pyelitis in children in recent years, only rarely had neonatal pyelitis been referred to. The author's brief clinical report was based on fifteen cases (thirteen males), he said, seen in private practice in the past six years. The disease was probably not uncommon, and its early occurrence in otherwise normal male infants lent support to the hematogenous route of infection. Bacillus coli was found in fourteen instances; Bacillus enteritidis in one. Symptoms were usually referable to the gastrointestinal tract or to the central nervous system. Continuous alkalinization of the urine proved successful in thirteen uncomplicated cases within six to ten weeks after diagnosis. In one fatal case death was due to Bacillus enteritidis meningitis; in the other fatal case the urinary tract showed a congenital stricture of the right ureter—a probable factor in the fatal outcome.

X Ray Treatment of Pertussis.—Dr. Lawrence Weld Smith, of Boston, presented an analysis of 850 cases of pertussis treated by x ray. The author said that his findings proved that this method of treatment was of value in reducing the number and severity of the paroxysms and in shortening the course of the disease; that the majority of the cases occurred under seven years of age (750 cases); that most of the cases (499) were presented in the paroxysmal stage; that the greatest benefit occurred in the paroxysmal stage, and especially in the younger cases; that early diagnosis could be established bacteriologically and by blood examination as the disease was accompanied by an absolute and relative lymphocytosis in eighty per cent of cases during catarrhal stage, and that suitable vaccines made from organisms with an agglutination titre of 1-1660 plus were effective prophylactically and if given in sufficiently large and frequent doses were of value therapeutically—suggesting that the immunization was quantitative.

The author believed that these observations suggested that by early diagnosis adequate quarantine for the actual infective period could be required with a concomitant decrease in the morbidity and mortality.

A Method for Eliminating the Etiological Organisms in Treating and Preventing Endocarditis in Children.—Dr. Myer Solis-Colen, of Philadelphia, said that endocarditis was caused, as a rule, by microorganisms or their toxins. Except in rare instances, these organisms were not eliminated by the removal of infected tissue or by the washing of an infected mucous membrane with an antiseptic or other solution or by the administration of drugs, important as these measures were. Vaccine prepared from all the organisms or from the predominating organisms present in an infected focus might fail to contain the etiological organism or might contain it in too small numbers, and hence be impotent in raising the patient's bactericidal power against it. In the pathogen selective method of culture only the organisms that were pathogenic for the individual patient grew up. Administration of a vaccine made from them destroyed their pathogenicity and infectivity for the patient both at the focus and in the endocardium.

Static Type of Peritonitis in the Athreptic Infant.—Dr. John A. Foote, of Washington, D. C., said that athrepsia or atrophy as shown by Marriott and Perkins displayed a wasting of the blood in its formed and unformed constituence, as well as alteration in its physical volume and flow. It had long been recognized that athreptic infants were very susceptible to infection, but not so well recognized that symptoms in such infections were not at all typical. Denzer's observations called attention to the frequent presence of pus in the aspirated peritoneal fluid of wasted infants, and surgeons, such as Downs, had noted the absence of clinical symptoms in infants where autopsy findings revealed peritonitis. Children who had passed infancy and who were weakened by intercurrent conditions reacted in much the same way as the athreptic infant.

Analysis of cases of intussusception collected by Hess, Hemmeter, Dunbar and others, showed differences in the symptoms of pain, vomiting, tumor and other dynamic manifestations. Study of the protocols of these cases showed that these symptoms were absent only in the weak, depleted and malnourished children.

Infections within the first month of life were not infrequently accompanied by static peritonitis. Reports of cases from Children's Hospital, Washington, D. C., included an appendiceal abscess in a three weeks' old infant reported by Dr. Charles Crawford, and several athreptic infants with static peritonitis from my own service in which typical clinical symptoms were absent.

The intraperitoneal injection of normal salt solution and its effect on body weight in static peritonitis had diagnostic value, the author said.

A case of static peritonitis in a six months' old boy, accompanied by intussusception with corroborative

Positive Diagnosis!

$5.00 Brings it to you — A Year to Pay

Win Confidence—

Doctor—Here is an equipment that will surely aid in winning the confidence of your patients, in increasing your efficiency and in widening the scope of your practice. With this famous Spencer Microscope No. 18H and the Practical Diagnostic Microscope Outfit, you have the instrumentalities for establishing Microscope diagnosis positively, without jeopardizing your reputation by waiting for more marked findings in the physical examination. Why continue in uncertainty?

New 1924 Model Spencer High-Power Microscope

With Large Fifty-Millimeter Body Tube and Side Fine Adjustment, Affording Photo-Micrographic Work and Projection.

This latest model, world-famous, genuine Spencer Microscope, with large body tube, is an outstanding example of Microscope perfection. The great advantage that this model offers is that if the time ever comes when you wish to take a picture of a specimen slide or project a slide upon a screen, this Microscope will do it while other Microscopes with the smaller size body tube will not. The advantage of the new side fine adjustment is that it greatly simplifies focusing, as the movement of the fine adjustment buttons is in the same direction as the coarse adjustment.

You Begin Practical Work the Day You Get It

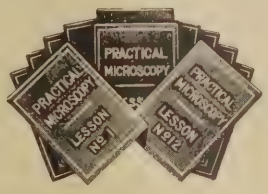
Everything is here for getting satisfactory results. The two text-books and the bacteriological chart make the work simple, the bacteriological set includes everything needed, and the instructions give the essentials of simplified microscopy.

The Free Outfit

which is included with this Microscope, is illustrated and briefly described on this page — it includes everything needed by the progressive physician to put the Microscope into immediate and profitable use. The instruction books and sheets are clear, practical and simple to follow. The accessories are complete — the very latest and best we can obtain.

Free Instructions

These valuable monthly instruction sheets, 12 in number, which we furnish free, teach you, step by step, how to use your Microscope, how to get results that will mean reputation, prestige and a better practice.



Free Manuals

Two volumes, "Diagnostic Methods" and the "Use and Care of the Microscope," by eminent authorities.

Bacteriological Chart

This large, fine bacteriological chart in colors to hang on the wall shows just how the bacteria look under the Microscope.

With this chart and this outfit you are equipped for a scientifically accurate diagnosis otherwise impossible in many cases.

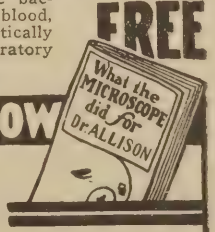
Bell Jar Cover

To protect your Microscope from dust and dampness — to make it convenient to use and to greatly enhance its appearance.

Complete Bacteriological Set — Free With This Great Microscope Outfit

With the Microscope we include an elaborate bacteriological set for the practical examination of blood, sputum, urine, body secretions, etc. — practically everything that is needed for efficient laboratory work by the physician—95 articles in all.

FREE



10 Days' Free Trial—You Take No Risk

Doctor, we leave it to you—you are the sole judge. Order this Microscope and complete outfit—try it for ten days—examine it, judge it, test it in any way you wish. Should you, for any reason, not wish to keep it, return it and we will cheerfully refund you every cent paid us. No questions—no quibbling. No ifs nor ands. Our proposition is so fair that, in justice to yourself and your patients, you cannot afford to pass it by.

Offered on Easy Rental Purchase Plan

Just $5.00 as a first payment—then you have a full year to pay the balance in such easy monthly payments that you will not miss the money. No delay — no red tape — just dignified man-to-man credit. Thousands have profited by this offer. Why not you?

Investigate — It Means Much to You

Right now — take the first step to obtain this practical, every-day help to better diagnosis. Be abreast of the times. 'Twill give you a new pride in your profession. Act — mail coupon for full information. Do it — do it today.

autopsy findings, showed that even such a typical disease as intussusception might be masked in severe prostration from intercurrent ailments. The use of pituitrin in intestinal atony in infants had a rôle in the production of nontypical intussusception. The author reported such a case with autopsy findings. The greater susceptibility of athreptic infants to infection and the occult nature of the symptoms manifested by such infants, especially in peritoneal infections, made the treatment largely prophylactic. The necessity for human milk and good hygiene in all extreme cases of malnutrition was evident.

PROCEEDINGS OF THE HOUSE OF DELEGATES

The House of Delegates met on Monday morning, May 25th, in the Hotel Traymore, and was called to order by the speaker, Dr. F. C. Warnshuis, of Grand Rapids, Mich.

Report of Secretary.—Dr. Olin West, of Chicago, presented his report as secretary, stating that the membership of the association, as enrolled on April 1, 1925, was 90,646, an increase for the year of 590.

Annual Conference of Secretaries of Constituent State Associations.—The annual conference of secretaries of constituent state associations was held in Chicago in November, 1924. Thirty-seven secretaries were in attendance. The editors of thirteen state journals were also present. There was, possibly, more of frank and helpful criticism, more of constructive suggestion, more of specific proposal for the adoption of definite programs of work than at any previous conference.

Change in Constitution and By-Laws.—The Committee on Reapportionment of Delegates at the Chicago Session recommended that the Constitution and By-Laws should be so amended as to provide for a possible increase in the number of delegates to be elected by constituent state medical associations; and that the regular triennial apportionment in 1924 should be made on the basis of one delegate for each 950 members or fraction thereof. These recommendations were approved by the House.

Official Visits to State and County Societies.—Whenever possible, in response to invitations, officers of the association have attended meetings of state associations and county societies. As a result of these official visits information has been brought back to the association's headquarters which has, in all instances, been acted upon in a manner that has been intended to serve to the advantage of the general membership.

REPORT OF THE BOARD OF TRUSTEES

Death of Dr. W. T. Williamson.—Dr. Walter T. Williamson, chairman of the Board of Trustees, died at his home in Portland, Ore., March 2, 1925. The Board of Trustees will, at a later time, present formal resolutions on the death of Dr. Williamson.

Retirement of Dr. Simmons.—Dr. George H. Simmons, having completed more than twenty-five years of honorable and distinguished service as editor and general manager of the association, retired from active duty, September 22, 1924, after presenting a characteristically thorough accounting of his stewardship. Dr. Simmons, in accordance with action taken by the House of Delegates, is now editor and general manager emeritus.

On November 22, 1924, after election by the Board of Trustees, Dr. Olin West assumed the duties of general manager. Dr. Morris Fishbein, by action of the board, became editor, and Mr. Will C. Braun business manager.

Exhibits.—Important work in the dissemination of public health information can be done through exhibits installed at the meetings of scientific and lay organizations, at expositions and at other places where the public is reached in great numbers. It is intended that the bureau shall accumulate material of this kind as speedily as its facilities will permit.

Exhibits of pamphlets, posters and charts from this bureau, the Council on Medical Education and Hospitals, and the Bureau of Investigation were made during the year as follows: At the annual meeting of the Superintendents' Section of the National Education Association in Chicago; at the National Congress of Parent-Teachers' Association in St. Paul; at the Minneapolis Health Exhibit in Minneapolis; at the annual session of the American medical Association in Chicago; at the annual meeting of the American Hospital Association in Buffalo, and at the annual meeting of the American Dental Association in Dallas. Material has been provided also for exhibits under the auspices of other organizations.

Radio Broadcasting.—Broadcasting of readings from *Hygeia* was continued monthly during the year from Station KYW, Chicago. Arrangements have been made through the secretaries of county medical societies in eight of the largest cities for similar broadcasting through radio stations in these cities.

Federal Income Tax.—Efforts were made to obtain relief through the Revenue Act of 1924 from the ruling of the Commissioner of Internal Revenue denying the professional character of traveling expenses incurred in attending meetings of medical organizations and of the expenses of graduate study. They were unsuccessful. Pending amendatory legislation, redress lies only through the Board of Tax Appeals and the courts. Unfortunately, however, most of the physicians who occasionally complain to the association of the injustice of the Commissioner's ruling have been unwilling to become parties to test cases to try out the issue, and an appeal cannot be taken in a hypothetic case.

Bureau of Investigation.—The interest of the medical profession and of the public in the work of the Bureau of Investigation (Propaganda Department) continues to increase. There was a small decrease in the number of letters received by the bureau from physicians during 1924, but on the other hand more letters were received from laymen during the year than ever before in the history of the organization; in fact, the inquiries received from laymen and from physicians were almost equal in number.

It will be noted that the name Propaganda Department has been superseded by the more descriptive term Bureau of Investigation. This change was made because it was felt that the new name more accurately described the activities of that department of the association's work.

Which Hypnotic?

Many Hypnotics—

Which To Use?

Which is the Best?

But how about a substitute for morphine when Pain causes Sleeplessness?

Is there a drug which is effective?

Has it been proven? Are there clinical data available?

Try ALLONAL and compare its value with that of other hypnotics—

IN the effort to provide a non-narcotic substitute for morphine many hypnotics have been evolved and are offered to the profession.

Certainly a serious question because of the many claims advanced by manufacturers.

Easily determined—the one proving the most useful in therapeutic range, most rapid in action, because quick action is invariably desired —and the safest in ratio to its hypnotic power.

Experience has proved the well known hypnotics usually ineffective in normal therapeutic doses where pain is a factor, because their function is limited almost entirely to inducing sleep.

Allonal was scientifically built for the purpose. It was not a chance discovery. It acts well not only in cases of simple insomnia but also in cases of the severest pain. In medical literature there is no other drug so extensively reported that is non-narcotic and yet resembles morphine so closely in hypnotic and analgetic properties.

Allonal was fully proven pharmacologically and clinically before it was offered to the profession. Published reports from many fields of medicine fully substantiate all the claims made for it.

Not only in the simple insomnias but also in the most difficult cases of pain or psychosis. Compare its action with that of any hypnotic. Prove for yourself the value of Allonal.

Literature and supply for trial on request

The Hoffmann-La Roche Chemical Works, New York

Makers of Medicines of Rare Quality

Council on Pharmacy and Chemistry.—The work of the Council on Pharmacy and Chemistry has been prosecuted along the lines that have been followed in previous years. Practically all the large producers of pharmaceuticals now find it possible and desirable to recognize the work of this council.

The Chemical Laboratory.—The Chemical Laboratory having been installed in permanent quarters in the new building, was able to work to much greater advantage during the latter part of 1924 than during the period when building operations were in progress. During the past year, the laboratory has elaborated for the Council on Pharmacy and Chemistry standards for practically all synthetic products submitted. It has questioned the chemical constitution of other synthetics, and manufacturers have been benefited by suggestions emanating from the laboratory, with the result that some of the newer products have been improved. An investigation of the various bismuth compounds used in syphilis is now nearly complete. Standards for chaulmoogra oil have also been worked out.

The Library.—The work done in the library of the association is much greater in amount and in scope than is generally realized. It is essentially a reference storehouse of current medical literature. The number of books on its shelves is not large, but more than 250 of the leading medical journals of the world are in file. More than twelve hundred inquiries were answered last year, not taking into consideration those which came by telephone or those submitted by the personnel in the association offices. In addition to a relatively large increase in bibliographic work, there has been a marked increase in the lending of periodicals, as the result, in part, of the extension of the library service to include domestic journals. In 1923, 475 journals, and in 1924, 760 were lent to physicians.

Therapeutic Research Committee.—The activities of the Therapeutic Research Committee of the Council on Pharmacy and Chemistry are expended mainly along the following lines:

1. The Organization of Therapeutic Research Requiring Collaboration: Work in this field is illustrated by the recent report of the Special Committee on the Toxic Effects Following the Use of Local Anesthetics. A Committee for the Study of Intravenous Therapy has been organized, with Dr. Cary Eggleston as chairman.

2. Support of Investigations of Problems of Special Interest to the Council: Work of this type is supported by the Therapeutic Research Committee when competent investigators may be secured, but almost inevitably much of it gravitates to the laboratories of those who are most interested in the topics proposed; thus, a considerable proportion of such work is performed under the immediate direction of the Chairman of the Therapeutic Research Committee. The grants that are made in this connection cover only a small part of the cost of the investigations, and go to pay for materials and apparatus required.

3. Support of Problems Submitted Independently: This has taken the form of contributions toward the material expenses of investigations that were somewhat beyond the ordinary budgets of the laboratories of the investigators.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The subjects dealt with in the foregoing repo may be thus summarized:

Medical Education.—1. In 1900, there wer 160 medical schools in the United States—mo than half the world's supply—including every var ety, from an openly conducted diploma mill up t the two or three which in standards and equipme compared favorably with any in the world. Mo of them were proprietary affairs conducted f profit. In many only a number of didactic, u graded lectures were given alike to the three four classes. The faculties of thirty or more we made up of from one to five practitioner teacher Many were entirely lacking, or seriously so in eith laboratories, dispensaries or hospitals, and in all b about thirty the entrance requirements were abse or nominal.

2. Now there is a smaller but more normal su ply of institutions, which in every way are well o ganized and efficient medical schools. Seventy-fiv or ninety-three and seven tenths per cent., have e trance qualifications similar to those of the rest the world; sixty three (seventy-eight and seve tenths per cent.) are integral parts of high grad reputable universities; sixty-two, or ninety-five p cent., of the four year colleges either have their ow teaching hospitals (thirty-four) or have liber privileges in other hospitals (twenty-eight) whereb efficient routine methods of clinical instruction a being given, and thirty (thirty-eight per cent.) no have groups of modern college and hospital building making them comparable with the best equipp medical schools of the world.

3. The higher entrance requirements, the co tent of the medical curriculum and the duration the medical course are not excessive, but represent tardiness on the part of this country in the adoptio of standards in our medical schools, long since re quired by the medical schools in Europe.

4. As a result of these great changes, the expens of maintaining medical schools has indeed great increased; and although students' fees have also bee increased, they cover less than one fourth of this.

5. New problems that have arisen as a result these great changes are: A complete reorganizatio of the curriculum; a development of more efficie methods of instructions; provision for a wider ele tion of subjects by the student, and the establis ing of a larger number of scholarships for the assis ance of deserving students without adequate finance These problems have been the main topics of di cussion at medical conferences during the last se eral years. Two years ago, also, a special commi sion was created to make an exhaustive study the pressing needs in medical education.

6. With the tremendous changes in social cond tions, due to the amazing developments in a score more of utiliarian and scientific fields and the great increased facilities for rapid transit between cit and country, there has come about an unprecedente trend of all classes of people away from rural t urban communities. These changes call for exte sive changes, also, in the methods of providing f public necessities in both city and country, includin the benefits of modern medical service.

Our twenty-five years of service to the Medical Profession in the making of

Electrically Lighted Surgical Instruments

and the fact that our instruments are made in accordance with the suggestions and with the co-operation of the eminent physicians and surgeons whose names they bear, is the best guarantee of their satisfactory character.

Both Specialists and General Practitioners

find genuine "E.S.I.Co." instruments invaluable in diagnosis, and our complete line includes such well known instruments as

Nasopharyngoscope—*Holmes*
Transilluminators—*Sullivan*
Bronchoscopic, Laryngeal and Oesophageal Instruments—*Jackson, Lynah*
Illuminated Eye Spud—*Snell*
Illuminated Nasal Snare—*Krause*
Illuminated Mouth Gag—*Jennings*
Urethroscopes—*Swinburne, Young, Gordon, Koch, MacGowan, Ballenger*
Cystoscopes—*Braasch, Young, Kelly, E. S. I. Co.*
Rectal Instruments—*Tuttle, Lynch, Axtell, Bassler, Beach, Buie*
Auriscopes
Nasal Specula
Tongue Depressors
Laryngoscopes
Vaginal Specula
Rectal Specula
Illuminating Batteries
Socket Current Controllers
Cautery Transformers

These instruments are described and illustrated in the Ninth Edition of our Catalogue, a copy of which will be mailed upon request.

To obtain proper service from our instruments, make certain you are using genuine "E.S.I.Co." lamps. For your convenience in ordering correct lamps, write for a copy of our Lamp Sheet.

Electro Surgical Instrument Co.
Rochester, N. Y.

Hospital Service.—7. The tremendous growth in the number of hospitals, the great improvement of hospital service, and the trend toward making hospitals accessible to all reputable physicians in their communities seem to offer a solution for the more serious problems of medical practice. The building of more of them in the outlying districts will help to secure a better distribution of physicians, and the development of their educational function will help provide graduate education or the physicians in their communities.

Graduate Medical Education.—8. Up to nine years ago, graduate instruction was given in institutions which, with a few exceptions, offered merely accumulations of ungraded and insufficiently described "courses" of doubtful value to the physician. Now there is a list of fifty institutions giving opportunities for graduate work, which, after careful investigation, have been found worthy of approval. 9. Instead of having to make a wild guess with regard to certain postgraduate courses which might or might not provide him with the instruction desired, the physician now has the information by which he is enabled to select promptly courses that will fit his particular needs.

Advertising of Graduate Schools.—10. Since the list of approved institutions was prepared, advertisements of graduate schools or courses which are not approved have been refused insertion in THE JOURNAL.

12. Graduate medical education can be placed within the reach of physicians of all communities, if the hospitals in those communities properly exercise their educational function.

Great Advances in Medical Education.—13. The tremendous increase in the amount of definite knowledge regarding the specific causes, methods of diagnosis, prevention and cure of diseases, in the last fifty years has been no less marvelous, although possibly less spectacular, than the development of the movies, the automobile, the aeroplane, the radio and other marvelous improvements in astronomy, physics and chemistry.

14. So rapid, indeed, have been the developments in all fields of human endeavor as to require not only a constant vigilance to keep informed regarding them, but also the devising of new methods whereby the essential needs of the public, both individually and collectively, can be supplied. Medical education and practice constitute only a part, although an important part, of the larger general problem.

THE EXHIBITS

The Hugh T. Young examining, operating, and radiographic table was shown by the Liebel-Flashein Company.

The Victor X Ray Corporation devoted their display mainly to showing the uses of their appliances in röntgenology and physiotherapy.

Mead Johnson and Company also demonstrated the many aids a physician could derive from their products. Mead's precision scales and their Mead service should prove of real worth.

Nystrom and Company, of Chicago, showed an excellent series of anatomical charts arranged conveniently for teaching or demonstration purposes.

An extremely interesting deep therapy diathermy lamp was displayed by H. G. Fisher and Company.

The Wappler Electric Company had a generous display of what seemed to be an extremely practical line of cystoscopic and urological material.

The Hoffman-LaRoche Works went to some trouble explaining the mode of manufacture and the uses of their many excellent products.

W. B. Saunders had included in their exhibit the deservedly popular Abt's *Pediatrics* and Bickham's complete *Operative Surgery*.

The Lederle Antitoxin Laboratories demonstrated the pollen diagnostic test for hay fever.

The Patterson Screen Company demonstrated a fluoroscope for finding foreign bodies in ordinarily difficult places.

New urological instruments were shown at the Bard exhibit.

The much discussed improved radio knife used by Wyeth and Kelly was shown by the Acme International X Ray Company.

The new portable electrical stethoscope perfected by the Western Electric Company was the centre of much attention.

William H. Horn showed various appliances useful in orthopedic and general surgery.

The Postum Cereal Company generously served its guests with samples of its various food products.

The Betz Company had an exhibit of equipment, furniture and instruments.

Lea & Febiger had a Chinese translation of *Gray's Anatomy* at their booth. It has not been widely read in this country.

Cushing's *Life of Osler* should prove popular. The Oxford University Press showed advance copies.

Horlick's Malted Milk Company have a new combination of Horlick's milk and barium sulphate for x ray diagnosis.

Metz stressed the various salvarsan products.

Carl Zeiss had an elaborate display of various types of microscopes and instruments for examining and treating divers parts of the body.

A new blood pressure device was demonstrated by the W. A. Baum Company, Inc.

The Winthrop Chemical Company featured some well known products, including veronal, luminal, and protargol.

The Merrell-Soule Company dispensed their fluid Klim to the thirsty, and their tasty Klim wafers to the hungry.

The Flanders-Day Company of Boston had ligatures for every possible need.

The Macmillan Company had an excellent assortment of standard textbooks.

Paul B. Hoeber showed in addition to his own publications and periodicals, an interesting set of historical volumes which attracted much attention. He also demonstrated the Bray film apparatus which is a convenient way of throwing photographs of anatomical and microscopical material on a screen.

E. Leity had a fascinating assortment of precision instruments, including those for photomicrography, blood counting, blood transfusion, and the estimation of sugar in the blood.

William Wood and Company had a most attractive exhibit of their well known and reliable medical books.

The Taylor Instrument Company showed the physician how to take care of his laboratory materials in an efficient fashion.

The National Dairy Council told of proper diet in the making of healthy persons.

The Maltine Company insisted on the profession knowing exactly what their various products contained.

Spencer supportive corsets made by Berger Brothers showed a large variety of their products.

Anesthetics manufactured by the Ohio Chemical Company are pure. They showed the reason why.

Bausch and Lomb featured their new capillary microscope, an excellent and convenient instrument.

Hynson, Westcott and Dunning demonstrated mercurochrome—220 soluble.

The Eastman Kodak Company showed some points of value in the use of the x ray and other films.

Mellins Food told of the uses and values of their products.

A new device, the Cambridge Recording Ophthalmoscope, should prove of immense value. It is based on the design made by Wertheim Solomonson of Amsterdam. A photograph of the retina is made without any alteration in the pupil. This should prove of great worth in brain tumors and in many other branches of research. The product is made in England, the New York works being at Ossining.

Practical Therapeutics

METALLIC POISONING FROM MERCURY, BISMUTH, ARSENIC, LEAD, COPPER, AND ZINC

ROBERT EMMET JAMESON, M.D.
Davenport, Iowa

Dermatologists, syphilologists, first aid physicians and industrial surgeons meet with cases of poisoning from the various metals named above, therefore all physicians should be familiar with the symptoms of these metallic poisons. The dermatologists, syphilologists and industrial surgeons especially should familiarize themselves with the symptoms of metallic poisoning and should learn the method of treating these cases, which was first worked out by French physicians and now in general use.

McBride and Dennie, of Kansas City, in an article published in 1923 (1) gave their experiences with sodium thiosulphate and the method of using it. Fournier some years ago pointed out that patients who were taking mercury while under treatment for syphilis, sometimes presented severe symptoms of metallic mercury poisoning, even when all the usual precautions of mouth hygiene had been attended to. Other patients may complain of itching and the more severe symptoms of arsenic rash which may even become alarming if the symptoms are not recognized and the drug discontinued and prompt treatment administered.

Formerly about all we could do was to stop the drug or keep the patient from coming in contact with the offending metals causing the untoward symptoms. Today, if we see a patient with salivation or the more severe symptoms of mercuric poisoning the drug is stopped and all acids are withheld from the diet and sodium thiosulphate administered either intravenously or by mouth or both. In cases of bichloride poisoning where the drug has been taken by mouth we should at once wash out the stomach with clear water until the poison is entirely washed fro mthe stomach, then fifteen gm. of sodium thiosulphate in 480 c. c. of water are administered through a stomach tube and allowed to remain in the stomach. The stomach tube is then withdrawn and immediately 0.3 gms. of sodium thiosulphate in ten c. c. distilled water are administered intravenously. For the following nine days the following doses of sodium thiosulphate are given intravenously: second day 0.45 gms. in ten c. c. of water, third day 0.6, fourth day 0.9 gms. in twenty c. c. of water, fifth day 1.2 gms. in twenty c. c. of water, on the sixth, seventh, eighth, ninth and tenth day 1.8 gms. in twenty c. c. of water. If the powdered form of sodium thiosulphate is used, the distilled water is put up in ampules ready for hypodermic use.

McBride, Dennie and others have obtained some splendid results in the treatment of metallic poisoning with this method.

I believe that every police station, all first aid stations, department stores, factories, hotels and railway depots should have sodium thiosulphate in ampules of assorted sizes in their first aid kits for immediate hypodermic use and in powdered form with proper doses, labeled so that it can be mixed with water for lavaging the stomach. City and county physicians and contract surgeons should know of the uses of sodium thiosulphate. In this way many lives may be saved.

When we consider the many hundreds who are daily exposed in the various trades to lead, copper and zinc and the hundreds of patients who are having either mercury or bismuth and the various arsenicals administered for the treatment of syphilitic infections we realize the importance of prompt and effective treatment. In the past we have not had any method of treatment to equal sodium thiosulphate. The redness, edema, serous exudate seen in salvarsan rashes and exfoliative dermatitis disappear and the dry desquamating stage is reached on the fourth to tenth day and the entire course of the condition is shortened from three to six months to as many weeks. In bichloride of mercury poisoning even more marked and prompt results are obtained with sodium thiosulphate. The abdominal pain, bloody stools, albuminous urine and even unconsciousness are relieved by the first dose of sodium thiosulphate, and after the fourth dose the patient is practically well.

REFERENCE

1. McBRIDE and DENNIE: *Archives of Dermatology and Syphilology*, January, 1923.

New Treatment of Impotence.—Lissmann (*Wiener klinische Wochenschrift*, June 26, 1924) classifies impotence into three groups: psychic, neurasthenic and those cases with no discoverable organic or psychic etiology. Psychic impotence requires psychotherapy plus the other usual methods of treatment, but the chief aim should be to convince the patient of his curability. The neurasthenic type of impotence must be treated along the lines of the neurasthenia, including the entire gamut of tonics, climatotherapy, balneology and gymnastics, psychoanalysis, possibly a change of occupation; treatment of the genital symptoms must be avoided most of all. In the third group the existence of any and all pathology must be excluded. The psychophysical sexual mechanism must be put absolutely at rest for several weeks and lukewarm brine baths, gymnastics, and a pelvic girdle should be advised. The list of aphrodisiacs is very long. Yohimbin produces marked congestion of the genitals, a diminution of blood pressure, an increase in tactile and genital sensitiveness and vasodilatation of the renal and dermal bloodvessels. It increases the reflex excitability of the sacral portion of the cord and the congestion of the genitals. This action of yohimbin may be accelerated by epidural injection combined with twenty c.c. of physiological saline solution. These injections may be given in the physician's office. An additional aid is a few applications of galvanization of the lumbar and sacral portions of the cord, with the anode above and the cathode below with a current up to four milliamperes.

Treatment of Mumps.—F. H. Thompson (*Clinical Journal,* August 27, 1924) says that the patient must be kept in bed, his bowels should be open daily, he should be blanket bathed daily and his mouth kept clean. The diet at first should be fluid, but as soon as the patient is able to chew he may be allowed fish, bread and butter, etc., to be shortly followed by ordinary food. No application to the parotid is necessary, but pain may be lessened by hot applications, though some sufferers find more relief from cold.

The tendency to orchitis is much increased if the patient is allowed to get up too soon, and he should not be allowed up until at least three or four days have elapsed since the complete disappearance of the swelling, for orchitis may lead to sterility. Should orchitis occur, the part requires support and protection and hot or cold applications. It is said that incision may prevent atrophy, and the operation is as follows: A two inch incision is made vertically in the tunica vaginalis, the organ brought out, and a dozen incisions, not over a quarter of an inch long, are made just through the tunica albuginea parallel to the long axis of the testis. If necessary the epididymis should be similarly treated. A drainage tube is then left in the tunica vaginalis and the wound closed round it, the scrotum being firmly bandaged.

Effects of the Intravenous Injections of Acriflavine.—Harvey Spencer (*Journal of Laboratory and Clinical Medicine,* February, 1924) states as the result of an investigation to determine the effect of acriflavine upon red and white cells, and the bactericidal action to be expected from the intravenous injection of the compound, that in a concentration of 1 to 2,000 or lower in physiological saline solution, it has no agglutinative action upon human erythrocytes. *In vitro,* acriflavine in concentrations greater than 1 to 8,000 in saline is lytic for human erythrocytes. *In vivo,* acriflavine injections to the amount of 0.1 gram to the kilogram of body weight (rabbit) induces a slight but transitory reduction in the number of the red cells, and a considerable increase in the number of the white cells. A single intravenous injection, or multiple injections, of the tolerated dose does not lead to an increase in the bactericidal action of the serum when tested against Staphylococcus aureus. White mice injected simultaneously with the tolerated dose of acriflavine and the minimal lethal dose of virulent pneumococci are not protected by the dyestuff.

The Value of Alkali in Dye Therapy.—Victor Burke and Irene Grieve (*American Journal of the Medical Sciences,* July, 1924) say that the bacteriostatic and bactericidal action of many of the dyes varies with the hydrogen ion concentration of the medium surrounding the organisms. With an increase in alkalinity there is, with but few exceptions, an increase in the action of the dyes for gram positive and gram negative bacteria. The fluids of the body may vary in their hydrogen ion concentration, causing the bactericidal action of the dye to vary greatly. The body fluids should be made alkaline by the administration of sodium bicarbonate, or the application of an alkaline wash before the dye is applied. Lactic acid, which is usually present in pus, reduces the action of the dyes. The bacteriotropic action of the following dyes can be increased by the use of alkali: Crystal violet, methyl violet, gentian violet, brilliant green, basic fuchsin, the flavines, and malachite green. The action of many other dyes of less importance is affected in the same way. The use of alkali will, in certain types of infection, prove beneficial in addition to the effect on the antiseptic power of the dyes. Controlling the hydrogen ion concentration of the body fluids may be utilized to check the growth of certain bacteria. Many of the factors in resistance and repair are more active in an alkaline medium.

Relief of Visceral Pains with Paravertebral Injection.—F. Brunn and F. Mandl (*Wiener klinische Wochenschrift,* May 22, 1924) report good results with the use of paravertebral injections of ten to fifteen c. c. of a 0.5 per cent. solution of novocaine without the addition of adrenalin in gallbladder and renal colics. Several patients with angina pectoris were also relieved for several months, some for only days. The injections must be made very carefully to avoid the spinal canal and the pleura. A needle ten cm. long is inserted three cm. from the midline and then turned slightly to the side to avoid injecting the rami communicantes. Renal colics require the injection to be made in the right thoracic segment. For angina pectoris the injections are made in the first to fourth dorsal segments and in paroxysmal tachycardia in the first and second dorsal segments. Injections should be made for angina pectoris only when all other therapeutic measures have failed. Paravertebral injection is a harmless and simple procedure.

Effect of Röntgen Rays upon Blood and Agglutinin Formation.—The following results were obtained by Carl Frei and Albert Alder (*Schweizerische medizinische Wochenschrift,* July 24, 1924) in the study of the effects of röntgen irradiation with large and small doses upon agglutinin formation in the guineapig:

1. Röntgen rays do not affect previously existing agglutinins.

2. In animals injured by röntgen rays the formation of agglutinins proceeds undisturbed, both with the lowest leucocyte counts and in the presence of severe injury of the blood system.

3. With simultaneous irradiation and immunization the irradiation appears to activate the formation of agglutinins, inasmuch as it occurs earlier and is more pronounced than in the immunization controls. In no case was an unfavorable effect observed.

4. The site of agglutinin formation is probably not the same as that of the blood elements, inasmuch as the formation of agglutinins proceeds undisturbed in spite of the most severe injury of the blood elements.

5. The blood changes seen after irradiation were the following: The intensity of the blood injury depends upon the duration of the irradiation. The lymphatic system reacts rapidly to the irradiation, the myeloid system more slowly and the erythropoietic system still more slowly. The rapidly developing diminution of the leucocytes probably depends upon a more rapid destruction of the circulating elements.

Historical Medicine

A Brief Synopsis of the History of Venereal Diseases

SAMUEL GORDON, M.D.
Philadelphia

The science of medicine is incompatible with suppositions. An idea to be accepted must be accompanied by ample proof of undeniable facts. It must be verified by microscopical findings, laboratory tests, röntgen ray photographs, Koch's postulate, at the autopsy table, or biological tests. But there are certain ideas, created in the investigating mind, to which the above named verifying agents are not applicable. What, then, should the man of those ideas do? Shall he, therefore, abandon his ambition, abolish his thoughts, and put a lock on his reasoning power?

The human mind resorts, then, to old documents, studies the ideas of his ancestors, and demands explanation even from skeletons that were buried thousands and thousands of years before. The questions we are about to discuss are three in one; that is, three questions, which were considered as one, until about a century ago. When was the Treponema pallida born? How old is the gonococcus? In what era did the Ducrey bacillus pay us its first visit?

These questions have given rise to controversy in the profession and no absolute conclusion has been reached so far.

Bloch in *The System of Syphilis,* Volume I, 1908, insists that there is no evidence of syphilis in the Eastern hemisphere previous to the return of Columbus with his sailors from Hayti about the end of the fifteenth century.

It is asserted by many physicians of Europe, that these sailors brought the disease from America and infected the inhabitants of Barcelona. In 1493 it reached Italy by the soldiers of Charles the Eighth, who besieged Naples with the intention of civilizing it and succeeded in syphilizing it. On the other hand, there are many other physicians and reliable investigators, among them such great authorities as Dupuy and Duchesne, who state that the venereal diseases existed long before that time, and that no evidence is not always compatible with no existence.

As it is not the intention of this paper to enter into the discussion, nor is it possible to do so within limited space and time, I will proceed to trace venereal diseases from their remote antiquity up to the present time.

J. Parrot, late professor of the faculty of medicine in Paris, asserts the existence of venereal diseases as far back as the Stone Age. This assertion is based on excavations, which were made in Solutre, in the region of Seine-et-Loire. It is a site definitely proven to be prehistoric from the findings of reindeer, horses, cut flints and remains belonging to the Gallo-Roman Merovingian epoch. In 1872 Abbe Ducrost found a female skeleton, which was examined by famous anthropologists, such as Broca, Parrot, and others. It was their opinion that this skeleton could be referred to the Stone Age. The two tibiæ of this woman presented exostoses along their entire length. After careful examination, Broca, Allier, Parrot, and Virchow pronounced it syphilitic. Another valuable proof of the existence of syphilis nearly five thousand years ago, can be obtained from the following fact. At a period, which equals the year of 2637 B. C., the Emperor of China, Hoang-ty, ordered for the benefit of his people, that all the medical documents should be collected and compiled in the form of books.

In 1863, Captain Darby, by the help of some native friends, translated these manuscripts. A full description of symptoms corresponding to the disease of syphilis was found in them; also a statement that mercury is the specific treatment for this disease.

It is worth while remarking, that the sons of Noah and their descendants, our ancestors, were at that time nothing but horrible anthropophagi.

There is no direct evidence of the existence of syphilis in ancient Egypt at the time of the Pharaohs 1400 B. C.

Almost all the hieroglyphic tablets, that were found and deciphered, deal with ordinary every-day occurrences. Nevertheless, the *Ebers Papyrus,* printed by Ebers in Leipzig in 1875, treats of medicine at the time of Rameses the Second. The translation was made by Chabas, a native, and it contains certain descriptions corresponding to the symptoms of constitutional syphilis. Definitely expressive and explicit on the subject of venereal diseases is the Bible. It indicates that gonorrhea and syphilis were frequent guests in the camps of the sons of Jacob. It also shows that the lawgiver, Moses, knew the malignancy of syphilis and its contagious powers. When his teaching of precaution was forgotten, his methods of prophylaxis not followed, and an epidemy of syphilis broke out, he adopted the most radical treatment that was practical under the circumstances, in order to save the whole community from becoming a prey to the disease, as we shall presently see.

The symptoms of the different forms of skin eruptions described in Chapter 13, of Leviticus, correspond to leprosy as well as to syphilis. It is extremely possible that the word "leprosy" employed in the Bible is rather a generic term covering various forms of skin disorders.

Chapter 15, Leviticus, considers the two varieties of urethral discharges. The first variety is the specific one. Not only direct contact with the individual is strongly forbidden, even to touch anything that came in contact with the sick one, produces an uncleanliness, which requires a thorough washing of one's body and clothes. The sufferer himself is unclean until seven days after the discharge completely ceases. He, then, washes himself and his clothes in running water and becomes clean.

The second variety is treating an ordinary sperma-

torrhea and requires from the afflicted nothing more than a good wash of his body and be unclean until evening.

Chapter 25 (v.1) Numbers: "And Israel abode in Shittim; and the people began to commit incest with the daughters of Moäb."

v. 3. "And Israel joined themselves unto Baäl Peör." This was the god of prostitution of Moäb. Almost every Asiatic country practised the socalled religious prostitution. The priests of those temples were always sure to have a full house. There was no necessity for special attraction to draw a crowd. The children of Israel, who had recently heard the seventh commandment "Thou shalt not commit adultery" thundered down from the smoking Mount Sinai, could not resist the temptation of Baäl Peör. What was the result?

Says the Bible: "Then the wrath of Jehovah made itself felt." Soon after an epidemic disease broke out and decimated the Israelites. Twenty-four thousand men became infected, and in order to stop the spread of the disease to all the camps, Moses was compelled to kill all the infected men.

In the description of the vengeance of Israel on the Midionites, Chapter 31, Numbers, where it is related that the Hebrews took the women captive, Moses reproaches them, saying:

"Are these not the women who have seduced the sons of Israel at the instigation of Bil'am, and who have made ye deny the Lord, your God, to make you sacrifice to Peor, from whom has come the scourge, which has stricken our people?" And an order was given to kill all the women who have known man. These words need no commentary. They speak for themselves and show us the character of that epidemic.

Chapter 28, v. 27. Deuteronomy: "The Lord will visit thee with the ulcers of Egypt, and with the hemorrhoids, and with the scab, and with the itch, whereof thou shalt not be able to be healed."

v. 35. "The Lord will cover thee with bad ulcers from the sole of thy foot to the top of thy head, upon the knees, on the legs, and thou willst not get well."

v. 59. "Thy sores will increase by the will of God, as also those thou hast given to thy progeny; then they will be large and persevering sores, the worst and most lasting lesions."

Note in this verse the indication for hereditary syphilis.

Proverbs, Chapter 6 and 7, mentions the dangers of syphilis caused by having intercourse with a prostitute.

Isaiah (785 B. C.), Chapter 3, v. 9. "The boldness of their face testifieth against them, and like Sodom they tell openly their sin, they conceal it not. Woe unto their soul, for they have prepared evil unto themselves."

v. 17. "Therefore will the Lord smite with leprosy the crown of the head of the daughters of Zion and the Lord will lay open their nakedness."

Ecclesiastes (2950 A. M.). "Whosoever joineth himself to adulterers shall become impudent and that rottenness and worms shall have him to heritage."

There are many places in the Bible, where this disease is directly or indirectly referred to, but for obvious reason I can not mention all of them.

It is almost impossible to trace venereal diseases among the Hindus (1000 B. C.) or among the Greeks before and after Christ or later among the Romans, without mentioning again the religious prostitution, which was practised by nearly all the ancient nationalities. The gods, which required this sort of worship, were: Lingam, Baäl, Venus, Priapus, Brahma, Vishnu, and Siva.

The last named was the main god in Hindu. One of the books of Vedas, the Hindu Bible, contains the practice of medicine.

Chapter 21 reads as follows:

"Thus the irritated humors produce disease: attacking the abdomen they produce difficulty in urinating. Attacking the penis, they produce functional trouble of that organ, venereal disease, alteration of the semen, and other diseases. If the cellular tissue is attacked, there will be: tubercles, tumors, painless swelling, cervical ganglia, and so forth."

This text reads like: gonorrhea, cystits, fistula, tumors at the anus, orchitis, gonorrheal, tuberculous or syphilitic epididymitis, gummata of the skin, indolent ganglia at the neck, etc. Note especially that the text separates gonorrhea from venereal disease and considers the discharge an alterated semen.

We are now approaching to examine the Greek medical works on venereal conditions. Surprising enough, the great Hippocrates, the father of medicine as he is usually called, who practised at the city of Cos (460 B. C.) does not speak directly of syphilis. All we find in Lecture 3, Section 21, of his book is the following:

"*In summer occur . . . Opthalmias,* pains in the ears, ulcerations of the mouth and rotting of the genitals."

Section 14. "Under the influence of Southern Winds there come moist ulcers, especially in the mouth and upon genitals."

This meager and deficient description from such a celebrated physicain has given a triumph to the opposers of the idea, that syphilis existed in those days. Astruc, especially, uses this fact in his argument.

Says the other side:

If lead poison was to be to him only colic; malaria, only intermittent fever; so it is possible that syphilis is only ulceration of the genitalia.

Galen of Pergamos (130 A. D.) describes symptoms resembling syphilis. During the Roman dynasty the practice of religious prostitution was continued. The temple of Isis, Venus Volupia, Venus Solacia, and especially the gardens of Priapus were constantly filled with worshippers.

The poets of that time describe in beautiful Latin verses the extraordinary and abnormal indulgence in women. They also portray all the symptoms of syphilis as an inevitable result.

Catullus describes male concubinage practised by young boys at the age of puberty, coaxed into it by their parents. The doctors of those days: Dioscorides, Oribosius, Aëtius, Alexander of Tralles, and Paulus Ægineta have not done any original work in the field of venereal diseases. They have followed their predecessors of the Greek School. The Arabian School completely eclipses that of Greece. Rhazes, a famous physician practising in Bagdad at the end

of the ninth century, describes venereal papules followed by tumors on the vulva or penis as a result of coitus. Ali Abbas at the end of the tenth century, Mesvé, Isaac, Avicenna, Avenzoar, Averroës and Albucasis, all famous physicians of the eleventh century, have described similar symptoms.

Mesvé tells us that the disease which was known as the Persian Fire was nothing but chancres.

Michael Scot (1214-1291) writes:

"When a woman has a discharge, if a man have intercourse with her, he has many opportunities of contracting an affection of bad nature on his penis. In addition it should be known that if conception take place at that time the product will be tainted with the diseases."

Note, that this author plainly indicates heredity of venereal disease.

Guillaume de Salicet, professor of Verona (1270) in his book *Surgery,* Chapter 53, describes crusts and ulcers of the legs as venereal disease. He also advises friction with mercury quenched with saliva. At present we quench the mercury with lard, which is infinitely more practical.

Gulielmus de Saliceto, a physician of Piacenza in 1270 states: A bubo or impostum of the groin arises for the most part from a cold humor, which is expelled from the liver to those places which are weak and empty. It may proceed sometimes from a hot humor and sometimes it comes from a fulness in the yard (*in virga corruptio*) contracted by lying with an unclean woman.

Bernard Gordon, professor of physics in the University of Montpellier (1300) says: "Diseases of the yard are numerous, following lying with a woman, whose womb is unclean, full of putrid sanies, virulence, etc."

Sylvaticus in 1317 says: "If you wish to preserve your organ from a virus, in case you should have reason to suspect your companion of being infected, wash yourself as soon as you retire with cold water to which vinegar has been added or with wine."

Beckett and Wagstaff (1399) state: "Joan de Gaunt mortus est ex talis putrefactione membrorum genitalium et corporis, sui causata per frequentionem mulierum."

Petrus de Argelata, of Bologna (1425) says: "The retention of the poisonous matter lodged between the glands and prepuce, after coitus with a foul woman, causes the part to become black and the yard mortifies."

Before I end the tracing of the Middle Age period, I must mention the fact that in 1495 a great epidemic of venereal disease broke out in Naples and has spread all over Europe. The Spanish physicians were the first to blame America for it. The blame was thrown on the sailors, who have returned with Columbus from Hayti as I have mentioned before.

Previous to the 15th century these diseases received no names. During the epidemic the following names were given: Morbus neopolitanus, morbus gallicus, mal de francois, gore, grande gore, verolle, and grande verolle.

Note, that though they believed that the disease was imported from America, yet they did not name it, Morbus Americanus. Sebastian Brant and Grunspeck named the diseases scorra pestilentialis.

The first one to name them venereal disease was a French doctor by the name of Jacques de Béthencourt, 1527.

Now let us sum up what we have learned so far:

1. Documents indicating the existence of venereal diseases with remote ages.

2. During the thousand years (Middle Ages) syphilis existed in an endemic state.

3. From time to time it disseminated itself, for reasons of debauchery and lack of hygiene, into outbreaks and received different names according to the impression formed at that time.

4. Leprosy was the name given to all skin diseases, syphilitic or nonsyphilitic. All authors of the fifteenth century agreed that the leprosy of those days was communicated by coitus.

5. The use of mercury, which the physicians were forced to accept from the hands of the empirics, constituted the tangible proof of the identity of the leprosy of the Middle Ages with the syphilis of today.

Has the world profited by the terrible epidemic of 1495? Has humanity taken a lesson with reference to hygiene? Have the people improved their manners and checked debauchery? History answers they did not. Morality has been corrupted just the same as before.

Fracastorius (1530) published a poem, in which he described the symptoms of syphilis so wonderfully, that no one of the present time authors can add anything more. He named this poem *Syphilis,* a name which was destined to remain. He had no doubt that the scabies and leprosy described in the Latin poems were all syphilis.

He recommended for treatment infusions of mint, hops, thyme, and guaiac. He also strongly advises sweating. "When one perspires, the rottenness leaves the body with the drops of sweat." These are his own words. He also speaks of purging and bleeding. But above everything he praises mercuric inunctions, which he pushes up to salivation.

In the following years, the mercuric inunctions were practised to such an extent, that the gums of the patients softened and their teeth fell out. The result was, that the patients rebelled against this treatment and the physicians were compelled to abandon this treatment for fright of losing their patients.

Paracelsus (1536) was the first one to proclaim that mercury was the only drug specific for syphilis.

Fernel (1548) corroborated the statement of Paracelsus.

Benoit Textor (1550) was the first to recognize two varieties of chancres. One without ulceration commonly called Apusthumous; the other is ulcerated and excoriated. He considers a chancre incurable and advises extirpation.

Gabriel Fallopius (1555) describes clearly the primary lesion and points out, that the indurated margin of the chancre is a pathognomonic symptom of the disease. He also had recourse to mercurial inunctions. The question: how long may the mercury treatment be pushed, was a matter of dispute through the whole sixteenth century.

The seventeenth century did not produce any new ideas in reference to venereal diseases.

Le Monnier (1689) is still under the impression that gonorrhea is one of the primary symptoms of syphilis. Though he advances a correct idea,

namely: a healthy woman having relations with an infected man, may transmit the virus to one or more, without being herself contaminated by it.

The first writer in the eighteenth century, Jacques Vercelloni attributes the disease to fermentation of the seeds.

Boerhaave, the Dutchman, (1728) states: that gonorrhea rarely occurs in connection with syphilis and, therefore, he thinks, that the symptomatology of syphilis has been markedly modified. To believe him, gonorrhea would even be a sort of vaccination against syphilis.

Dibon, two years later, determined that gonorrhea was never cured by mercury. Today we understand the reason, but the author at that time was greatly astonished at it.

Astruc (1736), physician to Louis the Fifteenth, wrote a celebrated treatise on venereal diseases. He believed in the existence of a virus. He divides the diseases into two stages: local and universal. Under the first, he includes: virulent gonorrhea and consequences, venereal buboes, chancres, verrucæ, and condylomata. Under the second stage he includes: diseases of the genitals, skin, mouth and nose, venereal pain, diseases of the bones, glandular and lymphatic tumors, diseases of the eyes and ears, and disorders of the functions.

We have now arrived to that period, in which, the most famous physician of his time, the enthusiastic experimenter, the celebrated author and teacher, John Hunter of England. He describes fully the initial lesion and establishes the pathognomonity of induration. Like Astruc, he also believes in a virus, and the virus may affect in two modes. Primary or locally and secondary or constitutionally. He has performed a great number of inoculations. Through a laboratory mistake, he inoculated himself with the virus of syphilis, believing it to be that of gonorrhea. When the result was a typical chancre, he proclaimed that gonorrhea and syphilis are caused by the same virus. He makes then the erroneous statement that if the virus comes in contact with mucous membrane the result is gonorrhea and when with skin a chancre would follow.

This error has clogged the wheels of scientific progress for fifty years. It has especially caused a death blow to the idea of Benjamin Bell, who gave reasons for the separation of gonorrhea from syphilis two years before.

Hernandez of Toulon (1810) survived the idea of Bell. He also created the theory of larvated syphilis in both sexes. In the beginning of the 19th century a curious theory has been adopted by some authors. Broussais (1815) denies the existence of a virus as the cause of syphilis and places this disease on the same line with scrofula. Ten years later his pupils Jourdan and Richard follow up the doctrine of their teacher and say: "Call it what you will but name it not virus." They regard the constitutional symptoms of syphilis not as a poison but merely as a sympathetic response to local irritation.

In 1830 we observe the existence of two schools. One school teaches that there are several identical viruses in syphilis. That it may start by chancre, gonorrhea, or bubo. The other school recognizes only one syphilitic virus and rejects certain venereal diseases as nonsyphilitic. The first school is known as Identists, the second, as Unicists.

M. Ricard belongs to the Unicists. We must admit that Ricard has ended the conflict, which reigned in science for fully three hundred years.

His definition of venereal disease is as follows: "All those affections, which are more or less, directly or indirectly, the consequence of sexual intercourse in whatever way affected." He distinguishes the virulent from the nonvirulent attacks. The virulent results in chancre and the nonvirulent, in chancroid.

In 1857 he acknowledges his errors, profits by the discoveries of others, adopts the idea of Bell and Hernandez, that gonorrhea and syphilis are two distinct diseases, and demonstrates the truth of it by a series of inoculations.

He also accepted the theory of the school of Lyons admitting the existence of mixed chancres. His division of syphilis into three stages: primary, secondary, and tertiary is now accepted all over the world.

There is a tendency to divide syphilis into two periods. One, the primary, embracing the period of incubation and morbid determination. The other, consecutive period, embracing the time of virulence and destruction.

The cause of this tendency is to overcome the difficulty, which we meet quite often under the present assumed division; namely; the fact that some secondary symptoms are found in the tertiary stage, and some tertiary symptoms are found in the secondary stage.

On the other hand, there is more difficulty and burdening on the mind of the student to differentiate the resolutive from the destructive period. For, it is plainly to be seen, that, while it is easy to recognize necrosis of the nasal bone or that of the hard palate, it is not so easy to recognize an exostosis or certain late manifestations of cutaneous syphilis.

An attempt has been made in 1852 by Auzias Turenne, followed by Sperino at Turin and Boek at Christiania to form a vaccine against syphilis. The attempt failed and those who have been inoculated have gotten syphilis. They would otherwise probably never have gotten it.

In 1878 the gonococcus was discovered by Neisser and gonorrhea is therefore termed Neisser's disease.

In 1889, Ducrey isolated a bacillus and Unna proved that this bacillus is the cause of chancroid.

In 1903 Metchnikoff and Roux have succeeded in reproducing syphilis by inoculating monkeys.

March 3, 1905, Fritz Schaudinn discovered the Treponema pallida in a syphilitic lesion.

In 1910 Ehrlich announced his famous compound known as 606 or salvarsan, which is at present adopted as the first attempt in the cure of syphilis.

One important result of the discovery of the parasite was the application of the method of serum diagnosis. Upon the fact that by the introduction into the system of parasites, there must follow a production of immune bodies in the blood, the Wassermann reaction is based.

Finally I must mention M. Mauriac (1883) who divides the history of syphilis into four periods:

1. Creative period; from the epidemy to 1508.
2. Dogmatic period; from 1508 up to John Hunter.

3. Experimental period; from Hunter to the nineteenth century.

4. Scientific period; embracing the nineteenth. Let us hope that the historian of the twentieth century will record the name of a great man, who will succeed in finding an immunizing agent against all forms of venereal disease to safeguard humanity.

The Seguins of New York; Their Careers and Contributions to Science and Education.—Dr. Charles L. Dana, writing in the *Annals of Medical History* for December, 1924, gives a short sketch of the lives of Dr. Edouard and Dr. Edward C. Seguin, with comments on their personalities and the contributions they made to science and education.

Dr. Edward C. Seguin was born in Paris in 1843. He accompanied his father to the United States in 1850, living first in Ohio. In 1863 the family came to New York City, where he graduated in medicine in 1864. He was a surgeon in the army until 1865, from that time until 1867, interne in New York Hospital. He studied in Paris from 1869-70, returning to New York in 1871, where he was associated for five years with Dr. W. H. Draper. He was lecturer in neurology at the College of Physicians and Surgeons from 1871 until 1885. During that time he established a clinic for nervous diseases in the Medical College, the first clinic of the kind established in the country. He was one of the founders of the American Neurological Association and of the New York Neurological Society. "He was one of the first, if not the first, to teach the value of very large doses of iodides and of aconite, hyoscine and nux vomica. . . . He claimed that he was the first to give hypodermics of water for pain." He believed firmly in the fact that neurology is a part of internal medicine, and was the founder of the *Archives of Medicine.*

Although Seguin was not a New Yorker by birth, nor even a college graduate, he very early achieved a position in his profession in the city, and a high rank at the College of Physicians and Surgeons when he was only twenty-eight. Dr. Dana writes that Seguin made a very deep and definite impression upon him, and that he believes he was perhaps the most important and useful factor in the development of neurology at that time. "This was because of his precise and careful methods, of his thoroughly scientific attitude towards clinical medicine, and his sincerity and honesty in connection with his patients and his work. . . . Happily this intense interest in clinical work was not inspired, as is often the case, mainly by a desire to make a diagnosis. Seguin was equally interested in trying to cure and help his patient."

Dr. Edouard Seguin, the father, was born at Clamency, France, January 20, 1812. He was educated at the College of Auxerre and St. Louis, Paris. He studied with Itard and later worked with Esquirol. In 1839 he opened a school for idiots, with a view to educating them, for he believed that often the brain is not diseased or abnormal, but only arrested. This institution, the first of its kind, was officially approved by the Académie des Sciences in 1844. After ten years of work in Paris, the Seguins came to the United States, and to New York several years later, where Dr. Edouard Seguin helped to organize the School for Defectives at Randall's Island. In 1873 he represented the United States at Vienna as commissioner of education in the matter of the organization of asylums for the blind, deaf, idiotic, aged and infirm. He was a prolific writer; his greatest work was his *Treatise of the Moral, Hygienic, and Educational Treatment of Idiots,* published in 1846.

The writer believes that Dr. Seguin was very nearly a genius. "He not only devised a new and successful method of education and treatment of a class previously neglected, but he had the intelligence to work out its practical details, developing and carrying out his system so logically and effectively that it quickly won world wide acceptance." He knew psychology and philosophy, was conversant with literature and the languages, and loved painting and poetry, writing very good verse himself. "He was very modest and retiring personally, very eager always to help others, and most generous and unsparing of self. He seemed always to be searching for ways to help his fellowman."

Surgical Operations in Ancient India.—In addition to minor operations, the Hindoos performed a certain number of major operations, among which was the amputation of limbs. They were acquainted with laparotomy, upheld in the case of intestinal obstruction; abdominal paracentesis in dropsy, vesical section, and even the Cæsarean operation. Intestinal suture in case of lesion of the intestines was accomplished by means of "clamps" of an animal nature: they made large black ants armed with strong mandibles bite the lips of the wound; then they removed their bodies, leaving the heads in place on the wound. The ablation of a cataract was performed through extraction, not couching. Hindoo surgical operations were among the most original and most perfected of antiquity.—(*Æsculape,* February, 1925.)

The Use of Tobacco in Medicine.—The time of the introduction of tobacco into Europe is difficult to place exactly. It is generally attributed to Nicot who presented some in 1560 to the Grand Prieur de Lisbonne and to Catherine de Medici; hence the names, nicotine, herbe du Grand Prieur, and herbe de la Reine. As to its use in medicine, it rose, after Dr. Georges Petit, to Francis II, who covered with ulcers, salved them with an ointment with a base of tobacco, of which Catherine de Medici gave him the formula: Fresh tobacco leaves, ground in a mortar, one pound; melt half a pound of clean pork fat to the consistency of ointment on a slow fire, and strain through linen.—(*Æsculape,* 1925.)

CONVENTION IMPRESSIONS

The seventy-sixth annual convention of the American Medical Association was a source of stimulus to the many medical men gathered at Atlantic City. The inspiration of the high level should carry on to the medical profession throughout the country. The various representative groups functioned smoothly. The coordination of the machine as a whole was splendid.

The exhibits were laid out in a most attractive setting on the Steel Pier. The long, double, central isle was flanked on either side by booths containing the latest developments in instruments of the newest design, physical apparatus for every conceivable function, up to a mechanical horse. There were vibrators for every little joint and ligament. There were magic lights for aches and pains. In fact, the apparatus displayed for physiotherapy needs were in keeping with the progress made in this field recently.

Of foods, there were many milk preparations for the infant, diabetic foods, food for gastric disorders, and foods to determine the type of disorder.

X ray and electrotherapy apparatus of many types were given special emphasis, the rays being placed on the new daylight screen.

A new and no doubt extremely practical device for the photography of the retinal image should find favor for the finer diagnostic points about which neurologist and ophthalmologist so frequently differ. A special field for this device should be in the diagnosis of progressive brain tumors.

A new absorbent cotton was shown which has a tremendous power of absorption. This will find favor among surgeons.

The principal progress shown by the exhibits was along mechanical or physical lines. There were no startling or well marked innovations in the field of new drugs. The substantial products were stressed.

The book publishers had attractive exhibits. Saunders, Appleton, Mosby, Macmillan, and Hoeber had prominent displays which attracted a great deal of attention. Hoeber had, in addition to his regular showing, a fair collection of most interesting historical books on medicine.

Among the scientific exhibits was that of Chevalier Jackson showing the menace of lye to children. He seems to have shifted his interest from the aspiration of foreign bodies to that of the treatment and prevention of lye burns, both of vital and everyday importance.

The heart exhibit featuring the work done by Williams at Columbia University was exceedingly well worked out and a fine piece of systematic scientific work.

The syphilitic exhibit, as well as many of the other exhibits, including the moving pictures and the fresh pathological specimens, showed little that was new to the well posted medical man.

On the whole, the exhibits were interesting and worthy of careful inspection.

THE NEW SURGERY

Among the papers of foremost importance presented at Atlantic City was the inspiring, if somewhat sensational, report made by Howard A. Kelly of Baltimore and some of his colleagues on the new surgery.

This work is founded on the principles laid down by George A. Wyeth, of New York. In the main it consists of the substitution of the electrocoagulation needle for the scalpel. Kelly told, very graphically, how and why he had used this method for over one year and had practically abandoned the use of the knife. He had found it of great value in the removal of various carcinomatous growths. An entire breast and lymph nodes had been removed without the use of the knife. Some of the advantages he pointed out were: The avoidance of hemorrhage, the simplicity with which the penumbra of a carcinomatous area was reached, the prevention of metastases by the sealing of surrounding lymph structures, the avoidance of trauma, a general insult to remaining tissue by the absence of sponging, clamping, and the general handling of tissue.

Another point of interest touched upon was the destruction *in situ* of distant lymph nodes by electrocoagulation. He gave an instance of a metastatic lymph node being destroyed in this fashion in the neighborhood of Poupart's ligament. He termed this process the explosion of the node, and showed how this could be extended to pelvic and abdominal surgery. Many hours could thus be saved in major surgical operations and he felt that the procedure was far more effective. He also gave several instances of the application of these methods to secondary invasions due to carcinomatous processes.

Great skill was required in the handling of the apparatus in order to avoid various mishaps, but

it was felt that these obstacles could be overcome. From all the evidence shown this new method of surgery should be epoch making and a more widespread knowledge of the technic seems highly important. These methods should revolutionize surgical methods. A wider use of it will undoubtedly bring many new points in its perfection.

THE INCREASE OF MEDICAL KNOWLEDGE

Increase of medical knowledge during recent years has come from researches in physiology and biochemistry rather than from investigations of bacteriology and pathology. It is in these fields of research, too, that the best results may be expected in the future. As a matter of fact, bacteriology is halted because a closer knowledge of the infective organisms and their biochemistry is required before advance can be made. As for pathology, it also waits largely on biochemistry, in that it only shows signs of progress as a study of the reactions of the body to disturbance, and in so far as it can express its phenomena in terms of biochemistry. Also, the pathologist is confronted by a task which has long hindered the improvement and accretion of medical knowledge, to wit, the elucidation of the question of the invisible viruses, which it is said, and indeed there is good reason to believe, are the originating causes of many of the most frequent and troublesome diseases, of which measles, whooping cough, mumps, encephalitis lethargica, and perhaps influenza, may be mentioned.

In this category may be included several of the animal diseases, as, for instance, foot and mouth disease, which inflict immense losses and some of which may be communicable to man. In this connection it is encouraging to know that the study of comparative pathology is gaining ground and that by its means and the use of the greatly improved microscope the causative factors of some of these hitherto infections of obscure origin may be discovered.

Physiology and biochemistry have given to the world within the past ten years or so valuable and for reaching new knowledge with regard to nutrition. In this direction progress has been most notable. The vitamines, while somewhat resembling the invisible viruses, in that they are more or less hypothetical, have enriched our previous knowledge as to diet. It may be more correct to say that our knowledge of the mineral salts, and the proportion of each which go to make up a healthy and adequate diet has been greatly augmented because it is believed on sound grounds that if in a diet the mineral salts are present in fairly proper proportions, the vitamines will be there as well. However, without attempting to split hairs, it certainly may be stated that our knowledge of the laws of nutrition, if such a term be applicable, has been furthered to a very appreciable extent.

Much has been added to our former knowledge on the causation of rickets. Lengthy experimental work, especially in Vienna during the semistarvation period of that city's recent history, has apparently confirmed views, to some extent, as to it being a disease of dietetic deficiency. Moreover, in America and in Great Britain this point of view has been elaborated and refined by dietetic experiments made with various animals. At the same time the dietetic influence on the causation of rickets has been almost overshadowed by retarding the effects which light and sunlight in particular, have been shown to exert on the development of this disease of faulty bone formation. It has been known empirically for many years, Hippocrates knew, that light had remarkable curative powers, powers which are still little understood.

Physiologists at the present time are active in analyzing the action of light in order to explain the why and wherefore of its surprising remedial and curative properties. It seems that vitamines may be present in light, that is, that there is an apparent interchangeability of light and vitamine action. Although some of those who have made a special study of rickets are inclined to exaggerate the baneful effects of the lack of light in the causation of rickets, the majority perhaps of investigators in this field hold that both lack of light and an inadequate and unsuitable diet are concerned in causing this crippling condition which has been a long standing curse in industrial and smoky cities. Rickets is not the only disease which is fostered and developed by a comparatively sunless atmosphere.

Tuberculosis is as much a disease of the smoky, dimly lighted slums as rickets and practically all chronic diseases, including that farspread and invaliding malady rheumatism, are to a greater or less extent injuriously affected by insufficient light. The results already reached by investigations in the field referred to above have been most encouraging, and give rise to the hope that disease, even in the near future, will be largely diminished and that the health of the people and the beauty of the country will increase in a corresponding degree. Another point which should be noted in this incomplete survey of the increase of medical knowledge, is the advance that has been made in clinical studies. Most of the chief contributions to medical science of the past few years have been the results of clinical investigations, for example, of the functions of the heart, the excretory efficiency of the

kidney and the regulation of the respiratory mechanisms of the body. And this progress has been rendered possible because investigations were carried out by men trained in the exact methods of physiology and biochemistry.

Further steps in the forward march of physiology and biochemistry will capture new positions from which successful attacks can be launched on the citadel itself. It should be borne in mind that successes in medical science although they may appear spectacular, are generally speaking the ultimate result of many years of patient and persistent labor conducted, as a rule, by many investigators in different countries. Often, unfortunately, the man who has found the keystone or done most of the spade work does not gain the reward which is his just due. Medical science is bound by no national limits and its discoveries are gifts to humanity and yet the laborer is worthy of his hire. In this respect again signs are more hopeful and it is being realized more and more thoroughly that it is for the good of all that the research worker should be rewarded generously. It may be added that it is in America the inhabitants are most alive to this aspect of the situation.

MENTAL AND PHYSICAL WORK

The report of "breakdowns from mental work" are frequent, but we wonder if this, like some other phrases used with common glibness, really has the meaning it seems to imply.

We are all so accustomed to pigeonholing things, and especially to building up impenetrable partitions between anything that savors of what we call material and anything that savors of what we call immaterial, that when we speak of mental breakdowns we consider that something has occurred altogether apart from a mishap of the physical machinery or because of something which happened to the physical machinery.

What is mental work and how does mental work differ from physical work? As an example of mental work, we are usually referred to what a child does in school. He is shown certain objects or pictures of objects and certain collections of marks, which are called names for these objects, he is impressed with through eyes and ears, and he reproduces vocally or tactually (by the use of muscles) these signs or symbols for objects. By repetitions he so impresses his brain cells that, on appropriate stimulation, they are able to react after an interval and again to carry out the muscular movements made in reproducing these symbols. There is a use of sense organs, nerve arcs, and muscles—a very physical performance not unlike the activities that went on ancestrally before schools or letters or even words were invented. There is nothing new about mental work, and nothing about such work that is not as physical as that of chopping wood or carrying water. It should also be borne in mind that wild animals in captivity, doing no mental work of this type, suffer from nervousness, sometimes go insane—have "mental breakdowns."

There are only two features in which this mental work of man differs somewhat from other work—in the acquiring and using of symbols (words) and in the more intense use of the eyes and of the smaller muscles for speech and for writing. Of these the use of the eyes as they were never before used is a most trying factor, and such use may result, as some of us are painfully aware, in a general upset of the whole organism.

There is a form of mental work which seems more lacking in physical accompaniment, such as the doing of mathematical problems without use of the eyes or fingers (mental arithmetic) or the planning out of some piece of work which will later be executed vocally or tactually. Again, however, physical machinery is at work and leading as much as following (after the button has been pressed by the original stimulus) in such production.

Studies recently conducted by Ilzhöfer of Munich as to the amount of energy used in mental work show that the caloric expenditure for such work is so trifling that the experimenter pronounced it hardly more than appreciable.

Why, then, mental breakdowns? Mental breakdowns are physical breakdowns which may, or may not, include a derangement of the cerebral machinery, but the wear and tear which brings them about can hardly be located in that organ at all. Eyestrain is a factor which leads to indigestion and a train of attendant evils, but probably, aside from this cause, the breakdown is brought about by reflex physiological disturbances originating in worries and anxieties connected with the progress or outcome of the work, which are really in no way a direct part of the mental work itself.

The bad hygiene, mental or physical, which often accompanies the intellectual life, does not tend to make mental breakdowns less frequent, while the general equipment in physique is an important factor.

Mental breakdowns are, then, physical breakdowns due to general stress and strain upon the whole organism arising from physical defect, inherited or acquired, and from bad physical hygiene or unhygienic attitudes toward life. After all, there is no such thing as mental activity without physical, any more than there is (to our knowledge) mind apart from body, though one is as immaterial as the other for aught we know.

TREND IN PROFESSIONAL HEALTH EDUCATION

Medical schools we have had with us for a long, long time. Perhaps they reached their culmination (in this country) as to numbers and attendance near 1890. At any rate, there were some 133 schools, about five thousand students, and around three thousand graduates. This was only about a decade after the discoveries of Koch.

Since 1890 the number of schools, the number of students, and the percentage of graduates has declined more or less steadily, until there are now some eighty schools, perhaps thirty-five hundred students and a thousand graduates. One can only speculate as to what the numbers might have been had nothing been done to improve the character of the schools and to make more difficult the acquirement of a state license. It is probable, however, that there would have been some decline in the number of schools and of graduates, through the influences of supply and demand. The very regulation of schools and courses which came about was, however, by way of a natural reaction, even if it came within a brief period and, chiefly, through the profession itself. There was real need for the reduction.

About 1906 the first professional course in public health was announced. It was one year in length, and few students were registered. The number of universities giving these courses of from one to three years' extent has now increased tenfold and the graduates (of all degrees) will now number annually about a hundred. Considering that medical schools date back for hundreds and thousands of years, the rapid rise of this new department of education is significant. However, like some other things apparently new, it grew from germs already developing within the medical school itself.

About forty years ago, or not long before medical schools reached their acme in quantity, though not in quality, there were some two schools of physical training or gymnastics in this country with a two year course and a handful of students. The number has increased with cumulative momentum, and, at last accounts, the number of special schools, of universities, colleges, and normal schools giving graduate courses (most of them of four years) had reached beyond fifty and seems likely to soon pass a hundred, while the students and graduates will number in the thousands. Moreover, these schools have changed from schools of gymnastics to schools of physical education and hygiene. More than this, there are now a few universities giving graduate courses in these subjects. This sudden sprouting of schools of this type was stimulated to some extent by recent state legislation for physical education and health teaching, and this, in turn, by the war; but as these things came by way of development, just as cyclones and earthquakes come through long existent causes, this phase of professional training for health work may be said to have been natural. The seeds were laid, on the one hand, by all previous wars (for every nation gets wonderfully worked up over the physical condition of its cannon fodder just after every great conflict), but, on the other hand, by farseeing prophets in education, from Rabelais to Spencer.

Another change, less spectacular, has come to pass in the education of the nurse. True, the courses in Public Health Nursing which have been evolved in the past decade have been postgraduate courses, but they are different from those offered by the old training in mere bedside nursing and lead to a variety of work in which the treatment of disease is but one phase.

It is interesting to note, in passing, that some mushroom schools of healers of sundry sort have arisen within the few decades we have reviewed. Their importance has been trifling from a pedagogical viewpoint, for they had little to teach, though much to gain (from tuition fees), and it is exceedingly interesting and significant that they have turned out people not interested in health. The products of these schools are intent on the treatment of disease, but not at all on its prevention.

In the midst of all this marvellous change the medical school still holds its important place, improved in every respect, and offering training, not only in the cure of disease but, through research and personal advice to the patient, in its removal from the earth so far as that is possible.

SANATORIUM TREATMENT OF TUBERCULOSIS

When sanatorium treatment for pulmonary tuberculosis first came into vogue, it was hailed far and wide as the greatest advance in the treatment of the disease that had ever been conceived and established. For several years after the inauguration of the sanatorium system this optimistic view prevailed. Gradually, however, doubts as to its efficacy crept in until now, while it has not fallen into disrepute exactly, its limitations are frankly recognized by all authorities on tuberculosis. Dr. Noel Bardswell, than whom few have had more experience of sanatorium treatment, speaking at a meeting of the Harveian Society held in Paddington last November, concluded that for working class patients, suffering from pulmonary tuberculosis, unless in the earliest stages, the sanatorium could not be regarded as an effective cure. A comparatively brief stay, as consumptives in an early stage usually make, is of little or no value and in the more ad-

vanced stage sanatorium treatment appears to be of no value whatever. Home environment, housing, occupation, habits, temperament and standards of living determine the consumptive's future to a much greater extent than does the period of sanatorium treatment.

In certain forms of tuberculosis, however, that is, tuberculosis of the larynx, Sir St. Clair Thomson spoke a good word for sanatorium treatment. In his opinion there was nothing else and nothing better. Of his own cases he could trace less than a dozen in which the patients had recovered without sanatorium treatment, whereas he had had 119 cases at Midhurst Sanatorium alone, where the larynx had cicatrized well and with few exceptions remained so. As he pointed out forty years ago, "There was never any expectation of cure. The appearance of tuberculosis of the larynx was the signal of death." The subject was of great importance, since it was calculated that today in England and Wales about one hundred and sixty thousand persons suffered from laryngeal tuberculosis. It was certainly the commonest specific disease of the larynx. In his youth such patients were tortured with insufflations and antiseptic powders, and he was accustomed to see the larynx as a horrible septic cavity. Nowadays, after a short time in a sanatorium, the larynx cleaned up in a way he had never seen in the old days. In his opinion sanatorium treatment was the first necessity; the next was rest for the voice either by whispering or better by silence. Silence was difficult at home even for the richest, but was easy in a sanatorium with other silent patients, and especially with trained nurses. The average percentage of cures of laryngeal tuberculosis by the three methods of silence, whispering and in selected cases the galvanocautery was 24.9 per cent., of the seventy-four patients selected for the cautery sixty-two per cent. were cured.

In reference to Dr. Bardswell's paper, Sir St. Clair Thomson said that the suggestion that if a case was sputum negative it was not tuberculous was absurd. Marked physical signs were quite sufficient evidence. He had himself seen a number of cases of laryngeal tuberculosis in which there never had been tubercle bacilli in the sputum. In many such cases the patients had recovered at sanatoria, but in many others they had waited for treatment till their sputum was positive and then died.

Sir William Wilcox said with regard to early diagnosis, he thought that one of the practitioner's greatest difficulties was that patients frequently waited too long before consulting a doctor. Another factor which had struck him as an examiner in medicine was the difficulty found by students in their five crowded years of study of learning the clinical signs of early phthisis. Many of them did not know how to percuss a chest, and some could not even percuss a heart. Percussion was a fine art, and too little respect was paid to it and to clinical signs, owing to the modern tendency to rely on laboratory work and x rays.

Dr. Dudfield, the president, said that the real solution of the problem was the improvement of housing conditions. At present these were almost hopeless for tuberculous patients; the overcrowding was horrible, and as a result of it much of the money spent on sanatoria was wasted.

Perhaps, the solution of the problem lies almost wholly in preventive measures, that is, in the improvement of housing, factories, and conditions of living and work generally. But a broadened sanatorium treatment, embracing colonies and workshops, may help the workingman in the early "moderately advanced" stage if he can be induced to stay sufficiently long to obtain real benefit. Even then the crux of the question is in housing and environment. On one point there is unanimity of opinion, that those advanced cases which are a menace to persons in propinquity should be isolated for safety's sake.

News Items.

New Officers of the A. M. A.—At the annual election, held on Thursday, May 28th, the following officers were elected:

Dr. Wendell C. Phillips, of New York, president-elect; Dr. Philip Marvel, of Atlantic City, vice-president; Dr. Olin West, of Chicago, secretary (reelected); Dr. Austin Albert Hayden, of Chicago, treasurer (reelected); Dr. Frederick Cook Warnshuis, Grand Rapids, Michigan, speaker, House of Delegates (reelected); Dr. L. Rock Sleyster, of Wauwatosa, Wisconsin, vice-speaker, House of Delegates (reelected).

Board of Trustees: Dr. Edward Henry Cary, of Dallas, Texas; Dr. Albert R. Mitchell, of Lincoln, Nebraska; Dr. David Chester Brown, of Danbury, Connecticut, and Dr. Joseph A. Pettit, of Portland, Oregon.

Council on Medical Education and Hospitals: Dr. Louis Blanchard Wilson, of Rochester, Minnesota; Dr. Walter Foster Donaldson, of Pittsburgh, and Dr. Ray Lyman Wilbur, of Stanford University, California.

Dr. John Shelton Horsley, of Richmond, Virginia, was reelected chairman of the Council on Scientific Assembly.

Next year's meeting will be held in Dallas, Texas.

Association for Study of Internal Secretions.—The ninth annual meeting of this organization was held at the Ambassador Hotel, Atlantic City, on May 26th, under the presidency of Dr. L. G. Rowntree, of Rochester, Minnesota. There were three scientific sessions. An interesting feature of the meeting was the symposium on the glands of internal secretion, the subjects discussed being the chemistry of the active principle of the glands of internal secretion, metabolic, circulatory, and psychical disturbances in diseases of the glands, and surgery of the glands. A resolution was adopted condemning the indiscriminate distribution of unproved gland products.

The American Academy of Physiotherapy.—The mid-year meeting of this society was held May 25th and 26th, at the Hotel Morton, Atlantic City. Of special interest was the symposium on ultraviolet rays, considering them in relation to growth and development, nasal and oral conditions, and tuberculosis; also the symposium on electrosurgical methods, discussing electrocoagulation, electrothermic methods, and endothermy.

American Life Convention.—The Medical Section of the American Life Convention will hold its fifteenth annual meeting in Louisville, Kentucky, June 2d, 3d, and 4th.

Nursing and Health Education.—The Teachers' College Bulletin, Columbia University, announces courses in nursing education, open to graduate nurses, and courses in health education, for teachers and supervisors.

Lincoln Hospital Closed.—Lincoln Hospital, in the Bronx, New York, which was founded eighty years ago for the care of negroes, but which has since cared for other patients, has closed, owing to lack of funds.

Tetanus Warning.—The Public Health Service has issued a warning regarding the use of bunion pads for shields or dressings for smallpox vaccinations, as several fatal cases of tetanus following vaccinations have been found by the Hygienic Laboratory to be due to tetanus bacillus in bunion pads.

Symposium on Hemorrhage.—The May 20th meeting of the Buffalo Academy of Medicine, section on obstetrics and gynecology, was devoted to hemorrhagic diseases of the newborn. Papers were read by Dr. Norman C. Benier, on etiology; by Dr. Marvin Israel, on symptomatology, and by Dr. Douglas P. Arnold, on treatment.

Veterans' Bureau Appointments.—In order to carry on the standardization of clinical and administrative service in the field, the Veterans' Bureau has assigned four supervisors to a tour of field duty: Dr. Winthrop Adams, for the New York district; Dr. E. P. Odenthall, New Orleans; Dr. Ord Everman, Chicago; and Dr. George O. Skinner, San Francisco.

Tuberculosis Association.—The New York Tuberculosis Association has changed its name to New York Tuberculosis and Health Association, to express more adequately its scope and purpose. A new activity of the organization is a community dental service, to be carried on in active cooperation with the Columbia School of Oral Hygiene.

Gifts and Bequests. — Washington University, St. Louis, will receive more than one million dollars for the establishment of the McMillan Eye, Ear, Nose and Throat Hospital, through the will of Sir W. Northrup McMillan, a former St. Louis capitalist.

The will of the late Emily A. Watson, one of the founders of the Orthopaedic Hospital for Crippled Children, contained many public bequests, among these being the following: Home for Incurables at Fordham, $50,000; Lincoln Hospital, $70,000; House of the Holy Comforter, Free Church for Incurables, $25,000; New York Skin and Cancer Hospital, $50,000; Fresh Air and Convalescent Home of Summit, N. J., $25,000; Montefiore Hospital, $25,000; Babies' Hospital of the City of New York, $25,000; Society for the Relief of the Destitute Blind, $25,000; St. Luke's Hospital, $25,000; Mount Sinai Hospital, $25,000; New York Association for Improving the Condition of the Poor, $50,000; New York Institution for the Instruction of the Deaf and Dumb, $30,000; Hospital for Scarlet Fever and Diphtheria Patients, $25.000; German Hospital and Dispensary, $10,000; Presbyterian Hospital. $10.000.

Hospital News.—The Knickerbocker Hospital, New York, broke ground recently for the first unit of its new buildings, to cost $500,000, at Convent Avenue and 130th Street. The total endowment sought for is $1,250,000.

A new addition to the Bon Secours Hospital of Baltimore, built at a cost of $300,000, has recently been formally opened.

The St. Louis City Hospital has constructed a three-story building for its radiology department, at a cost of about $100 000. Twenty-two rooms are provided, and a personnel of sixteen.

The New York Homeopathic Medical College and Flower Hospital reports that nearly $800,000 has been raised toward a million dollar endowment fund for drug research.

The Jamaica, L. I., Hospital, is opening a new five story addition. When plans are completed, this will be a hospital representing an expenditure of about one million dollars.

The New York Orthopedic Dispensary and Hospital is building an addition which will increase its dispensary space and also contain rooms for thirty-two private patients. This hospital has also opened a branch at White Plains, with rooms for thirty-five adults, in connection with its convalescent service for patients with joint tuberculosis. With these additions a total of some three hundred patients can be cared for.

Convalescent Care.—A meeting is announced to be held under the joint auspices of the Public Health Committee of the New York Academy of Medicine and the Hospital Information Bureau of the United Hospital Fund, Thursday, June fourth, at four o'clock, at the Academy, for the presentation of reports on standards of care and management of the convalescence of medical, surgical, pediatric, and neurological patients.

Columbia Appointments.—The following promotions in its medical staff were announced on April 25th by the trustees of Columbia University: Dr. Robert A. Lambert was named professor of pathology and director of the School of Tropical Medicine in Porto Rico. Dr. Nathaniel R. Norton, now associate in diseases of children, was appointed professor in that department. Donald H. Cook, Ph.D., was appointed associate professor of chemistry and was nominated to the board of trustees of the School of Tropical Medicine for appointment to the professional staff of that school. The following assistant professors were raised to the grade of associate professor: Dr. William C. Johnston, pathology; Dr. William C. von Glahn, pathology.

Society News.—The Harvard Medical Society of New York City has elected the following officers: President, Dr. Clarence W. Lieb; vice-president, Dr. Thomas E. Lavell; treasurer, Dr. Joseph C. Horan; secretary, Dr. James R. Lincoln.

Representatives of five national otolaryngological associations, at the invitation of Dr. George E. Shambaugh, recently met in Chicago and organized the board of directors of the American Board of Otolaryngology, as follows: Dr. Harris P. Mosher, Boston, president; Dr. Frank R. Spencer, Boulder, Colo., vice-president; Dr. Hanan W. Loeb, St. Louis, secretary-treasurer; Dr. Thomas E. Carmody, Denver; Dr. Joseph C. Beck, Chicago; Dr. Thomas H. Halsted, Syracuse, N. Y.; Dr. Robert C. Lynch, New Orleans; Dr. Burt R. Shurly, Detroit; Dr. Ross H. Skillern, Philadelphia; Dr. William P. Wherry, Omaha.

The American College of Radiology and Physiotherapy, at its recent meeting in Chicago, elected the following officers: Dr. John S. Coulter, Chicago, was chosen president-elect; Dr. Harry E. Steward, New Haven, Conn., Dr. Walter Scott Keyting, Salt Lake City; Dr. W. B. Chapman, Joplin, Mo.; Dr. Disraeli W. Kobak, Chicago, vice-presidents; Dr. Roy W. Fouts, Omaha, secretary, and Dr. Edwin C. Henry, Omaha, treasurer.

Personal.—Dr. John L. Kantor, of New York, spoke on constipation before the Lackawanna County Medical Society, of Scranton, Pennsylvania.

Dr. S. S. Goldwater, of New York, spoke at the dedication of the Butterworth Hospital of Grand Rapids, Michigan. Doctor Goldwater had served as consultant during its planning.

Dr. Louis Tulipan has been appointed chairman of the special committee on new members of the Medical Society of the County of New York, to succeed Dr. Maximilian A. Ramirez, who recently resigned.

Dr. George Draper of New York spoke on Observations on the Relation of Human Constitution to Disease, before the Atlantic County, New Jersey, Medical Society.

Dr. Raymond F. C. Kieb, superintendent of the Mattewan State Hospital, is to attend the International Prison Conference, in London, as delegate.

Dr. Edward O. Otis has been presented with a silver loving cup in recognition of six years' service as president of the Massachusetts Tuberculosis League, and has been made honorary president.

Dr. William E. Caldwell of New York spoke before the Atlantic County Medical Society on Source of the Pathological Findings in Stillbirths and Neonatal Deaths.

Dr. William W. Keen, of Jefferson Medical College, Philadelphia, has been elected a foreign honorary member of the Royal Academy of Medicine of Belgium.

Dr. Jonathan Pearson, Director of the Division of Tuberculosis of the New York State Department of Health, has resigned to enter private practice at Baldwin, Nassau County, New York.

The knighthood of Dannebrog, the highest honorary order of Denmark, has been conferred on Philip P. Jacobs, Ph.D., of the National Tuberculosis Association.

Joseph V. dePorte, professor of mathematics and statistics of the New York State College for Teachers, has been appointed director of the division of vital statistics for New York state, to succeed the late Dr. Otto R. Eichel.

Foreign Correspondence

VIENNA LETTER

(From our own correspondent)

VIENNA, *April 29, 1925.*

THE SCARCITY OF TENEMENTS AND THE OCCURRENCE OF NEUROSES AND PSYCHOSES IN VIENNA

Dr. Margit Herz has carefully studied the anamnestic data afforded by the patients of the neurological and psychiatric clinic of the Vienna University. She says that beyond the frequent mentioning of deficient nutrition she has frequently heard also about deplorable housing conditions. Crowding into furnished rooms, sometimes three and even four families, and flats suitable for one family only being occupied by three families, produced a situation conducive to immorality, litigation between husband and wife, jealousy scenes, sleepless nights, in fact, all the factors which go to create the socalled nervous habit, ending in various nervous and psychical manifestations. Dr. Herz proves with numerical data that the present social conditions are responsible for a great number of the mentioned mental diseases. In the female section of the clinic, during the last two and a half years, out of 4,703 patients there were eighty-seven in whom the question of housing had an important bearing on the occurrence of the disease. In about 240 cases the difficulty to get a suitable tenement had acted as the provocating agent of the mental trouble. In nine cases very severe depression developed, ending in attempted suicide, which was frustrated by relatives, and others near at hand; in others excessive restlessness and even furiousness developed. In twenty-five cases the psychosis turned into paranoia (paranoia magnans, paranoic shizophrenia). In some cases true melancholia developed; among these there were some in whom the existence of housing difficulty as a cause could not be proved. In several unfortunate women epileptiform fits made their appearance; every one of these involved the unpleasant occurrences by reason of their fright from requisitioning.

This unfortunate solution of the housing difficulty is causing very distressing conditions in the socalled successor states, that is the small states which have received the cutoff parts of the late Austro-Hungarian monarchy. In these parts nominally the new rulers place their own national officials in all public offices, and in the towns for these new inhabitants parts of existing larger tenements are requisitioned. Of course, the new tenant thus displaced in a tenement is, in most cases, tyrannizing the whole house, he being a member of the ruling nation, while the boss, the original tenant, is only a late enemy. Family happiness, peace between wife and husband, are the sacrifices of this unblessed state of affairs. This is a much cheaper way of solving the housing question than to build new houses, which is hindered instead of being encouraged. For instance, in Transylvania, a big territory, formerly part of Hungary, now owned by Roumania, the late Hungarian population would willingly build new houses, but for an order issued by the Ministry of Internal Affairs, which order enacts that the favor which was granted to builders of new houses by the late Hungarian state, consisting of exemption from state taxes (and there are still the late Hungarian laws prevailing in Transylvania), is annihilated, and also the assurance from the part of the state of being exempted from requisitioning, the only point that would encourage people to build new houses.

THE RECOGNITION OF FOREIGN DIPLOMAS IN CZECHOSLOVAKIA

The Karoly University in Prague has petitioned the Czechoslovakian Ministry of Public Instruction to grant to the university the monopoly right of being the only university in the land where the nostrification of foreign diplomas is executed. According to the petition the other university of Prague, the German University, cannot be held competent in arbitrating whether the candidate is well versed in the use of the language of the state, and whether he is reliable from civil and national points of view. In so doing the Czechoslovakian ministry would introduce a kind of numerus calausus (percentage norm), inasmuch as only one per cent. of the number of the total, in Czechoslovakia promoved doctors would be allowed to apply for nostrification, and in proportion of the ratio of the different nationalities living in Czechoslovakia as stated by the last census.

INSULIN IN THE TREATMENT OF CANCER

At a recent meeting of the Vienna Medical Society, Dr. Silberstein, lecturer at the Vienna University, assistant at the clinic for experimental pathology, gave a lecture, in which he described his experiments on animals as to the relation of carbohydrate metabolism to cancer. He was induced to make his experiments by the findings of the German biochemist, Otto Warburg, who had established that cancer cells decomposed much greater quantities of grape sugar than was needed by normal tissues. With this fact the relation of cancer and sugar metabolism came into the foreground. Now Dr. Silberstein experimented with insulin, in order to ascertain its effect upon the cancerous organism. He experimented with mice, causing cancerous growths on their backs by painting them frequently with coaltar. It was striking that the mice thus treated reacted upon insulin injection before the appearance of the first cancer node, quite differently from those not treated with coaltar painting. The former showed a much greater sensibility to insulin, inasmuch as one sixth to one half of the letal dose has killed them.

If the artificially produced cancer nodes are excised, fresh cancer nodes make their presence in the animal after a shorter or longer interval. The new nodes appear at different places of the body. Dr. Silberstein has observed the action of prolonged insulin application upon these animals and he could establish the fact that the cancer nodes have shown either a very protracted development, or they did not grow further at all if insulin was administered for a good length of time. If, however, the animal was given the greatest doses of insulin endurable after the excision of the cancer nodes, recurrences

were striking by their absence in fifty per cent. of all cases. According to this finding it is possible to render a cancerous organism more resistant to the extension of the cancerous growth by administering large doses of insulin. Dr. Silberstein requested the audience to assist him by placing at his disposal human excised cancerous tumors. He also advised that in cases of inoperable cancers they should try to apply the greatest possible insulin doses. With regard to the still hopeless state of cancer therapeutics, the good results attained by Silberstein on animals are at any rate encouraging further study on human subjects.

NEOSALVARSAN DEATHS IN ROUMANIA

The Roumanian daily press has written sensational articles—for want of sufficient competency in the matter—on some fatalities which have occurred in the Bucharest military hospital lately. Some papers have been so tactless as to intimate that the Germans sell to Roumania poisoned neosalvarsan as a "revenge." The university committee that has been sent out to investigate the matter has verified that three officers, a major, a captain and a lieutenant, the alleged victims, were suffering from grave organic diseases, the major and the captain from advanced locomotor ataxia and the lieutenant from diabetes. The members of the committee opened some vials taken from the chemical laboratory of the military hospital, and exposed the contents to the action of the air until oxidation took place. They afterwards inoculated two rabbits with the preparation and neither of them died. The committee passed its report to the Ministry of Public Welfare and closed with the statement that although very rarely fatalities are inevitable with the administration of neosalvarsan, nevertheless according to the present viewpoint of science and practice neosalvarsan is the specific remedy for syphilis. The Hamburg Court of Justice brought sentence last year against over forty persons proved to have falsified neosalvarsan.

X RAY DEATHS IN THE DRESDEN STATE CLINIC

In the State Clinic at Dresden two women have sustained such severe x ray burns, while being treated with deep penetrating rays, that both succumbed in great agony. The Court has sentenced professor Dr. Lahm, the director of the clinic, to 3,000 gold marks fine (about $750), while the junior surgeon who performed the treatment, and his assistant, a nurse, were sentenced to two months' imprisonment for manslaughter.

COMPENSATION FOR A DOCTOR INFECTED WITH TUBERCULOSIS

A junior physician of the Krankenhaus am Friedrichshain in Berlin has sued the city of Berlin for compensation, having become infected with tuberculosis while doing service in the tuberculous section of the hospital. He demonstrated that there were unhealthy conditions in that section, and that little had been done to prevent the possible transmission of infection. Up to the present three physicians and eight nurses have contracted consumption. The Court has brought sentence in favor of the doctor and ordered the city of Berlin to pay all his expenses for treatment, including half year's stay in Davos, Switzerland, and at the same time has obliged the city to pay him an annuity for his whole lifetime, and besides this has ordered the urgent restoration of the hospital in such a wise that similar sad occurrences could not take place in the future.

VIENNA HYGIENIC EXHIBITION

The international hygienic exhibition, arranged by the world famed hygienic institute in Dresden, was opened on April 28th.

LONDON LETTER

(*From our own correspondent*)

London, *April 14, 1925.*

MANCHESTER RADIUM INSTITUTE

At the annual meeting of this Institute, which was held on April 2d, the attendance was the largest on record, and the report presented by the radiologist, Dr. Arthur Burrows, showed that of 843 patients registered, 776 received treatment, the remainder being found unsuitable. The total number of cancerous patients treated was 577. A considerable improvement of immediate symptomatic cures was noted. At the end of the year 153 patients were described as well and 288 improved. Ninety-three cases of malignant disease, exclusive of rodent ulcer, were rendered free from symptoms and signs of disease. The number of rodent ulcers treated was 101, and of these 53 were well at the end of the year. The total number of outpatient attendances was 6,234, and the number of inpatients 966. Of the twelve beds for inpatients eight are used for non-paying patients. Last year the expenditure exceeded the income by £855. Sir William Milligan, honorary secretary and treasurer, said that they were probably a long way from the actual cure but they were definitely arresting the disease for periods of three, five, and seven years among people pronounced by the most competent surgical authorities as inoperable and incurable.

SIR HUMPHRY ROLLESTON REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE

Sir Humphry Rolleston, reelected recently president of the Royal College of Surgeons, has been chosen to fill the place of the late Sir Clifford Allbutt as Regius Professor of Physic in Cambridge University. Sir Humphry Rolleston, it need hardly be said, is eminently fitted to succeed his friend, Sir Clifford Allbutt, to this highly honorable position. He is an extremely cultured, learned man and collaborated with Sir Clifford Allbutt in editing the *System of Medicine* which is known by Allbutt's name and which has won a world wide reputation.

BOOKS

A second edition, thoroughly revised and added to, of Sir Kenneth Goadby's *Diseases of the Gums and Oral Mucous Membrane* has been published recently by Mr. Humphrey Milford, Oxford University Press. The book is probably the best ever written on the subject and is profusely and artistically illustrated. Two new features have been introduced—a chapter on vaccine therapy and a section on toxic heart. In the part dealing with toxic heart the author had the cooperation of Dr. Strickland Goodall.

Book Reviews

DIGITALIS AND ITS ALLIES

The Action and Uses in Medicine of Digitalis and Its Allies. By Arthur R. Cushny, M.D. New York: Longmans, Green and Co., 1925.

Professor Cushny has been actively identified with researches on digitalis of the past thirty years. A book from his pen, summarizing our present knowledge of the pharmacology and therapeutic use of digitalis and its allies, is assured an eager reception. A careful perusal of this monograph fully justifies the anticipations and expectations of the reader. The introductory historical chapter is followed by a detailed consideration of the action of digitalis on the frog's heart and on the mammalian heart. One chapter is devoted to its action on the blood pressure and on the bloodvessels. The author again emphasizes the well known fact that in therapeutic doses digitalis has no pressor action. There is a careful review of the extracardiac action of the drug.

The section on digitalis in therapeutics is very clear and comprehensive. Dr. Cushny does not advise the routine treatment of pneumonia with digitalis but prefers waiting until some special indication is presented. He points out that while digitalis is contraindicated in partial heart block, it may be useful in complete block. He commends the Eggleston method of quick digitalization in urgent cases, but advises the slower method when the symptoms are less pressing.

A well selected and comprehensive bibliography of 559 titles is appended. The printer's makeup of this tabulation deserves special commendation. Dr. Cushny's monograph should find a wide circle of readers among physicians in all fields of medicine, as well as among medical students.

SOCIAL PSYCHOLOGY

Social Psychology. By Floyd Henry Allport, Associate Professor of Psychology, University of North Carolina. Boston, New York, Chicago, San Francisco: Houghton Mifflin Company; Cambridge: The Riverside Press, 1924. Pp. xiv, 453.

Social psychology has been approached in a peculiarly illuminating manner through an examination of individual psychology. This in turn is thoroughly studied in the genetic upbuilding of a personality in its adjustments to the environment in answer to its needs. The individual is not born equipped with fully formed reactions, instincts ready to hand for loving his parents or entering into large social relations. All his social habits must be learned. These depend upon the conditioning processes by which the individual is surrounded; they are the personal reactions to the stimuli which are presented to the individual from the earliest hour. The importance of the sex relation to the personality is considered in its broadest sense and as a farreaching one in the socialization of the individual. The training of the child, or better his "conditioning," for the proper sex adjustment is especially well set forth, though the author's slight change in terminology from Freud's exposition of child sexuality seems scarcely necessary. He attempts to point a distinction between "Freudian facts," which he accepts, and "Freudian theory," into which he has read some unnecessary and nonexistent grounds for objection. On the whole the book enters both widely and deeply into the emotional and behavioristic factors which belong to the development of a personality and reveal that personality to be indeed, as the author states, largely a social fact. It is a vital presentation of psychological material in an eminently practical form.

YELLOW FEVER

Experimental Studies of Yellow Fever in Northern Brazil. By Hideyo Noguchi, Henry R. Muller, Octavio Torres, Flaviano Silva, Horacio Martins, Alvaro Ribeiro dos Santos, Godofredo Vianna and Mario Biao. Monograph No. 20 of the Rockefeller Institute for Medical Research, August 9, 1924.

This monograph describes the isolation of Leptospira icteroides from cases of yellow fever in the interior of Bahia; the pathogenicity and biological properties of the Brazilian strains; and immunological studies. 0.0001 c. c. of the antiicteroides serum prepared in horses with strains of Leptospira icteroides of Ecuadorean, Mexican, and Peruvian origin protected guineapigs against one thousand minimum lethal doses of a Brazilian strain.

VASCULAR VARIATIONS

Traité des Variations du Système Artériel. Pelvis et Membre Inférieur. Par le Dr. Louis Dubreuil-Chambardel. Paris: Masson & Cie, 1925.

This presentation is based on the study of hundreds of cadavers at the medical schools of Tours under Le Double. The notation of departures from the normal or, better, the usual arrangement and distribution of nutrient bloodvessels, is of recognized practical importance for the surgeon and clinician. The classification and, if possible, the explanation of such anomalies cannot fail to interest the student of comparative anatomy, the biologist, and all of those who, to quote the preface of Prof. A. Nicholas, *"curieux de dépasser les faits, y chercheront matière à spéculations sur l'origine des variations."* The author, a pupil of the anthropologist, Manouvrier, has found in embryology a key to many if not all of the vascular variations noted.

NERVOUS DISEASES

Nervenkrankheiten. Die wichtigsten Kapitel für die Praxis. By Prof. Dr. Hans Curschmann, Rostock. Klinische Lehrkurse der Münchener medizinischen Wochenschrift, Band 2. München: J. F. Lehmann's Verlag, 1924. Pp. 228.

Curschmann has not been afraid to point out in an emphatic style—brief sentences, direct, pointed statements, exclamation points when necessary—that he is writing of a subject of utmost importance not to the specialist alone. He drives home the fact that the general medical man must know of the existence and much of the nature of the disorders of the nervous system and still more important of the psychic personality. For all these he meets constantly in his medical service and their recognition and treatment may be neglected. The survey given is a comprehensive one though comprised in a small and convenient space. Not only are the facts presented in a manner to be easily grasped for practical use of them but the emphasis is well distributed upon the most important points of diagnosis and significance of the symptoms presented. The au-

thor's view is always that of a dynamic organism presenting symptomatic reactions, never that of one interested only in describing isolated disease entities. This is particularly manifest in the important field of the psychoneuroses, in hysteria, to choose a striking example. Yet here one feels some disappointment that the author has not given fuller etiological explanation on the basis of the dynamic struggle of the personality, which would have led also to fuller therapeutic suggestion. Has his reluctance to follow Freud blocked him just where he had promised most?

PHYSIOLOGICAL CHEMISTRY

A Laboratory Manual of Physiological Chemistry. Elbert W. Rockwood, M. D., Ph. D., and Paul Reed Rockwood, M.D. Fifth edition, revised and enlarged. Illustrated with four colored plates and forty-three text engravings. Philadelphia: F. A. Davis Company, 1924. Pp. 413.

This edition has been thoroughly revised, new methods inserted, and the text brought up to date. It is a very good laboratory guide for the use of those who are studying physiological chemistry for the first time.

ROCKEFELLER INSTITUTE REPRINTS

Studies from the Rockefeller Institute for Medical Research, Volumes LI and LII. New York: The Rockefeller Institute for Medical Research, 1924 and 1925.

These bulky volumes totalling about 600 pages each contain the collected reprints of articles which have appeared in various journals during the year from the Rockefeller Institute for Medical Research, and most of which have been abstracted in these pages.

BACTERIOLOGY

Handbook of Bacteriology for Students and Practitioners of Medicine. By Joseph W. Bigger, M.D. (Dublin), F. R. C.P.I., D.P.H. New York: William Wood and Company, 1925. Pp. 413.

This is a short textbook of bacteriology of somewhat limited scope. It is not quite suited for independent student work in the laboratory, as the directions are not sufficiently detailed for the average student to carry out the procedures without a good deal of help from the instructor. The illustrations are sufficient, and the press work good.

MICROMETHODS

Microméthodes et Semi-Microméthodes appliques aux Analyses du sang et des humeurs. By Dr. Durupt. Paris: A. Poinat, 1924. Pp. 234.

This useful little pocket manual contains directions for performing most of the current micro-analytical procedures. For the laboratory worker it will prove a serviceable guide.

ELECTRICAL CONDUCTIVITY

La Conductibilité Electrique due Corps Humain. Par André Strohl. Paris: Masson et Cie, 1925.

The author's studies, under Prof. Weiss at Strasbourg, are of great interest, clinically as well as experimentally. He reviews the history of investigations as to the nature and degree of resistance of living tissues to various types of electric currents, and to varying intensities and modalities. Working with a ballistic valvanometer, the passage of a current of constant voltage was found to be attended by marked variations in intensity, due largely to polarization of the tissues. The studies of Philippson on changes in electric conductivity accompanying cadaveric changes in muscles, similar variations in germinating plants, and in anaphylactic shock, the observations of Watermann on polarization in malignant growths, are suggestive, in this connection, of the wide application of Strohl's careful measurements and their possible bearing on medical science.

PEDIATRICS

Clinique Médicale des Enfants. Affections de l'Appareil Circulatoire. Par P. Nobécourt. Paris: Masson et Cie, 1925.

The author has made numerous contributions to the science and art of pediatrics, notably his volume on cardiopathies in childhood. The work under review is by no means a repetition, as it deals as Nobécourt himself reminds us, more with *malades* than with *maladies*. He details their histories—family, past, and case—describes the methods employed to arrive at a correct diagnosis; points out the difficulties met with, and presents the therapeutic indications. In common with his renowned predecessors, Corvisart, Potain, and Henri Roger, the author calls attention to the frequency of cardiac affections in infancy and childhood, the possibility of latent lesions, and of affections with slight symptoms if any. The relation to rheumatism, tonsillar foci, and bacterial infections are also considered. The book is illustrated with a large number of tracings of percussion findings, all reduced uniformly for purposes of study and comparison, and with radiographs of the heart area.

THE BLOOD

The Blood: A Guide to Its Examination and to the Diagnosis and Treatment of Its Diseases. By G. Lovell Gulland, C.M.G., M.A., B.Sc., F.R.C.P.E., and Alexander Goodall, M.D., F.R.C.P.E. With twenty-nine text illustrations and sixteen colored plates. Third edition. New York: E. B. Treat and Company, 1925. Pp. 424.

The third edition of this text does not show any great changes from the previous ones. A few cuts have been changed, and additions have been made to the bibliography. It seems odd to find a chapter on Status Lymphaticus in a book on diseases of the blood, and certainly more recent references to the treatment of this condition by x rays could be found than 1910. The chapters on malaria and blackwater fever have been rewritten and much improved thereby.

EXPERIMENTAL MEDICINE

Handbuch der viologischen Arbeitsmethoden. Unter Mitarbeit von 500 bedeutenden Fachmännern herausgegeben von Geh. Med.-Rat Prof. Dr. Emil Abderhalden, Direktor des Physiologischen Institutes der Universität Halle a.d. Saale. Berlin, Wien: Urban & Schwarzenberg, 1924.

In Abt. XIII, Teil 2, Heft 2 of this encyclopedic work, E. Friedberger dilates upon the technic and nature of the Pfeiffer phenomenon, which consists of the breaking down of pure cultures of micro-organisms that are introduced locally into the bodies of experimental animals and the microscopical study of this process from time to time in specimens taken from the site of introduction. The history and nature of this phenomenon, its practical utility and the technic are given in most minute detail. L. Michaelis describes the technic, practical application and theory of acid agglutination. Both of these articles are extremely technical and valuable chiefly

to the laboratory worker. C. von Pirquet and H. Koch write about the various types of local tuberculin reactions and their indications in man and animals. This monograph is very practical.

In Abt. IV, Teil 8, Heft 5, K. Amberger treats of the methods of examining alcohol and alcoholic beverages (wine, beer, brandy and cordials), C. Griebel on the microscopical study of tobacco and substitution products, and R. Kissling on the chemical study of the latter. This number is highly technical and of value to laboratory workers on the analysis of foods.

Abt. V, Teil 2, Heft 6 is devoted to the methods of formulating medical statistics, written by F. Printzing. In it the statistician will find much of value.

Abt. V, Teil 3B, Heft 2 contains some articles on the functions of special organs. B. Aschner writes about the technic of experimental investigation of the hypophysis and midbrain, H. Peiper describes the method of extirpating the adrenals in different animals, W. Kolmer describes some experimental studies on the pineal body and S. Fränkel writes about the demonstration, estimation and production of the internal secretions of special organs and about their decomposition and synthesis. From the very nature of this work it is too technical for the physician.

THEILHABER'S FIFTIETH ANNIVERSARY

Beiträge zu Problemen der Gynäkologie und des Karzinoms. Festschrift zum 70. Geburtstag und 50 jährigen Doktorjubiläum Hofrat Dr. A. Theilhaber in München, gewidmet von Prof. Edelberg, Prof. Fichera, Dr. Galant, Prof. Grudew. Dr. D. A. Gudim-Lewkowitsch, Dr. L. Hirsch, Prof. v. Jaschke. Doz. A. Jordan, Prof. Kakuschkin, Prof. Liepmann, Geh.-Rat Opitz. Dr. Rieger, Dr. S. A. Selitzky, Dr. Felix A. Theilhaber, Dr. Wladimirsky, Dr. Fr. Wolff. Berlin: C. F. Pilger & Co., Medizin. Verlag. Pp. 205.

This *Festschrift* was published to celebrate the seventieth birthday of A. Theilhaber, the gynecologist, and the fiftieth anniversary of his activity in medicine. A short résumé of his medical writings is given. Opitz writes about the approved theories on the origin and curability of cancer. Edelberg contributes an article on cellular immunity and the spontaneous cure of cancer. Fichera reports on his oncological studies on cancer. Rieger discusses carcinoma and blood supply. Galant discusses gynecological questions of the day, such as gynecological psychotherapy, artificial impregnation, the Kielland forceps, gynecological pediology, cellular immunity of the sexual cells and impregnation, and the course of investigation and the advances in gynecology. Kakuschkin takes up the subject of eugenics and gynecology. F. A. Theilhaber gives a critical review of bloodletting. Wolff discusses the fundamental principles of vaccine therapy in gonorrhea of the female. Selitzky takes up the subject of the clinical application of normal horse serum and of Ringer's solution. Liepmann's subject is metropathy of the uterus. v. Jaschke discusses the subject of the symptomatology of retroverion flexion of the uterus. Hirsch describes the operative treatment of dysmenorrhea according to Theilhaber's method. Selitzky and Jordan each write about symmetrical dysmenorrheal dermatitis, a toxicosis of menstruation. Grusdew discusses relationship between the high position of the uterus and Hirschsprung's disease. Gudim-Lewkowitsch writes about uterine hemorrhages associated with the hemorrhagic diathesis and the dysfunction of the ovary. Wladimirsky discusses dermoid cysts of the ovary with fat balls. Theilhaber himself contributes an article on cellular immunity in its effect upon the occurrence and treatment of constitutional and infectious diseases. An extensive bibliography is appended.

TISSUE CULTURE

The Technic of Tissue Culture In Vitro. By T. S. P. Strangeways. Cambridge: W. Heffer and Sons, Ltd. 1924. Pp. 80.

For those who wish to attack the many problems help for which the possibility of growing mammalian tissues in plasma offers, this is a valuable and practical guide, and one which will enable the research worker to carry on a good deal of investigation without further information. It should be supplemented, however, by the reading of Rhoda Erdmann's *Praktikum,* which contains a great deal of information which this brief exposition does not.

Tissue Culture in Relation to Growth and Differentiation. T. S. P. Strangeways. Cambridge: W. Heffer and Sons, Ltd., 1924. Pp. 50.

This little book gives a survey of some of the facts which have been observed during the culture of tissues *in vitro.* It might well be a good deal more detailed than it is, although the author states that it is simply the elaboration of his notes for a series of lectures he delivered at Cambridge. Very little reference is made to the work of the Lewis in this country, or of Rhoda Erdmann in Germany. A good deal more evidence than Strangeways offers should be brought forward before the statement can be accepted that "cells growing *in vitro* after exposure to x ray are permanently modified, and that new types of cells can be experimentally produced which, throughout an indefinite number of generations, may be said to breed true."

Medicoliterary Notes.

Two illuminating articles of unusual significance to those interested in the prison and penal problem are published in the *Atlantic Monthly* for April and May. They are entitled The Pound of Flesh, and Justice, and are written by a woman of exceptional intelligence and culture sentenced to a term of "nineteen years of hard labor," who signs herself Alice Thornton.

* * *

A movement to establish many more playgrounds for the slum children of London has been started. It will be fostered by a new organization called the National Playing Fields Association, which has begun already its propaganda work.

* * *

Dr. Frederick F. Russell, general director of the International Health Board of the Rockefeller Foundation, recently returned to this country from a tour of the Holy Land, reports that the war in Palestine on the malaria carrying mosquito has been so effectively waged that the greater part of the population of cities has been freed from all danger of infection.

* * *

According to recent press reports, London is building a new medical centre comparable to that which New York is erecting at Broadway and 168th Street. The nucleus of this new institution is the New University College Hospital made possible by a gift from the Rockefeller Foundation donated last year. When the new hospital is

npleted, it will be one of the best equipped plants of kind in Great Britain. The buildings already include well known laboratory for scientific medicine, a matery hospital, and surgical wards of one hundred and enty beds. One of the most generous of the individual ıors has been Geoffrey E. Duveen, who has given the for a new Royal Ear, Nose and Throat Hospital.

* * *

Boston will open in October a repertory theatre, which l be neither a state nor municipal institution, but a ic playhouse run by a quasipublic corporation. It proes to follow the example of Continental municipal atres in supplying to its patrons a varied and changing gram of dramatic entertainments based on the best terial from all countries. The Boston theatre will be exempt and so cannot be run for profit.

* * *

Every year about eight billion cigars are manufactured the United States, or about one for each resident to oke on Sundays and holidays. Even the imposing num- of cigarettes produced—sixty billion—means less than a day for each person, but the tobacco output also ludes one hundred and twenty million pounds of plug, million pounds of twist, and two hundred and fifty lion pounds of smoking tobacco. The surprise of the acco industry is that forty million pounds of snuff are l manufactured, although the habit was supposed to re passed. It means a consumption of nearly half a ınd per annum per capita. The tobacco imports besides luded nearly sixty million pounds of leaf and five million ınds of cigars and cigarettes.—*New York Times.*

* * *

The city of Buffalo has recently organized a Mental giene Council which is the outgrowth of the Committee Mental Hygiene of the Council of Social Agencies of t city.

* * *

The "dangers" to the theatrical profession from the adcasting of plays and other entertainments seems to as much in the lime light in Great Britain as in this ntry. A. N. M. writing for the *Manchester Guardian* ıs up the almost obvious conclusions of the discussion very much the same manner as has been done in the ited States. He writes: "All the protests in the world not prevent the encroachments of broadcasting upon the ma. These matters are not in the hands of sensitive ists who are jealous about their art. Broadcasting ıpanies are commercial companies, and they will not il because a number of contributors to the Playgoer's mposium think they are dangerous. We shall hear a d deal presently about the art of the broadcast play, possibly clever people will contrive to make something it. I don't think it can have any great effect upon more serious and talented of dramatists unless it be t they are hard up and the broadcasters bid high for ir degradation."

* * *

Bernard Shaw's play, *Saint Joan,* which was recently hdrawn after a start at the International Theatre in ris in deference to "certain clerical and patriotic susıibilities," has reopened at a very exclusive little playse called the Theâtre des Arts. The Russian company ducing it are reported to have spoken the lines with so ad an accent as to be at times unintelligible. Neverthe-, the play is pronounced a marked success, with nothing it to wound the most sensitive French patriot. The risians are particularly delighted with Shaw's portrait the ultra-British Earl of Warwick.

* * *

Robert Louis Stevenson's birthplace in Edinburgh at 8 ward Place will be opened by the Stevenson Club of nburgh as a memorial house in which his manuscripts other relics will be kept and exhibited for future erations. Contributions for a memorial fund to come the purchase of the house are being asked for.

* * *

A recent Epidemiological Report of the Health Section the League of Nations Secretariat shows that the llpox fatality rate increase is not confined to the United tes. In England, Spain, Switzerland, Algeria and Tunis re has been a marked increase in the prevalence of disease during the winter season. The report states "the gradual increase of the fatality suggests that a nge of type has taken place, as the fatality ratio is usually highest at the beginning of an epidemic, while the contrary has been the case here."

* * *

Recent books of interest to physicians are *The Challenge of Childhood,* by Dr. Ira S. Wile (Thomas Seltzer); *The Neuroses of Nations,* by C. E. Playne (Allen & Unwin, London); *Behaviorism,* by Dr. John B. Watson (The People's Institute, New York); *The Inheritance of Mental Diseases,* by Dr. Abraham Myerson (Williams & Wilkins Company); *Handbook of American Prisons,* prepared by the National Society of Penal Information (Putnam); *The Retarded Child: How to Help Him,* by Dr. Arnold Gesell (Public School Publishing Company); *Youth in Conflict,* by Miriam Van Waters (Republic Publishing Co.).

* * *

Denmark has recently recast its whole penal code. The new Bill of Punishments which is soon to go into effect abolishes legal practises that have been in vogue for hundreds of years. Capital punishment is abolished—it has not been enforced for nearly half a century—life imprisonment ceases to be a mandatory sentence even for first degree murder; it is imposed only for an attempt upon the life of a sovereign. The longest sentence that a judge can impose for other cases is one of eighteen years. Among crimes for which punishments are reduced are those against the safety of the State, against begging, petty larceny, and vagabondage. Penalties are increased for cruelty to animals, assaults upon women, and children, and for business frauds. New "crimes" are "public incitement to speculation" and "the making of incitement to emigration a business." Punishment is abolished for matrimonial infidelity, and under special circumstances exemption may be granted when one person kills another at the latter's request to end hopeless suffering or to fight against an incurable disease.

* * *

Novels announced for immediate publication by the George H. Doran Company are *Mayfair,* by Michael Arlen; *Wolf,* by Albert Payson Terhune; *Helen,* by Edward Lucas White; *Cruel Fellowship,* by Cyril Hume; and *Serena Blandish, or the Difficulty of Getting Married,* by "a Lady of Quality." Early in July Doubleday, Page & Co. will publish Joseph Conrad's posthumous novel, *Suspense,* in a de luxe edition limited to 377 copies. This is a story of Napoleon upon which Conrad was engaged in writing at the time of his death.

* * *

The new school of tropical medicine which Americans are building at San Juan, the capital of Porto Rico, will be ready for opening in the Fall. This school, while complete in itself, will be nucleus for other units. One of the principal objects will be the establishment and promotion of Panamerican friendship and interests. Although the causes and methods of treatment of malaria and hookworm are known, these diseases are still to be reckoned with in tropical regions, and there will be special departments in the new university for their study.

* * *

The April number of the *Harvard Advocate* is full of clever fun, for it is a parody issue, the cover of which imitates that of our radical friend, *The Dial.* The May issue of the *Forum* is one of unusual interest. Arthur Symons, the English critic, undertakes to name what are in his opinion the fifteen "finest novels." There is a debate between William L. Rogers and Tasker Howard Bliss on Shall America Arm? and another on America and Roman Catholicism, third in the series; the second of Jules Bois's articles on Religions of America—Theosophy; and some good stories.

* * *

Pamphlets recently issued by the National Committee for Mental Hygiene are A Plea for Greater Frankness in Dealing with Those Who Are Mentally Sick, by Ransom H. Sartwell, M.D.; Dispensary Contacts with Delinquent Trends in Children, by Esther L. Richards, M.D.; Psychiatric Treatment and Probation, by Bernard Glueck, M.D.; Feeblemindedness, by Walter E. Fernald, M.D.; Suggestions for Reading in Mental Hygiene, by Kathleen Ormsby and Frankwood E. Williams, M.D.; Some Undesirable Habits in Children and Suggestions as to Treatment, by Jessie Taft, Ph.D. and others. Any of these pamphlets may be obtained for a nominal sum from the National Committee for Mental Hygiene, 370 Seventh Avenue, New York.

Abstracts from Current Literature

BLOOD AND LYMPH GLANDS

Further Studies on Blood Grouping.—C. G. Guthrie and J. F. Pessel (*Bulletin of the Johns Hopkins Hospital,* April, 1924) confirm and extend their earlier observations concerning the existence in the human blood of at least three isoagglutinins and the corresponding isoagglutinogens: A fourth isoagglutinin (D) has been demonstrated in the serum of one member of group II in association with isoagglutinin A. Isoagglutinin D was not found in the serum of any other blood in the series including one member of group I, another member of group II, one member of group III, and three members of group IV. The corresponding isoagglutinogen (d) has been demonstrated in the red cells of one member of group III. It was not present in the six other bloods in the series, but has since been found in the erythrocytes of six additional members of group III in association with isoagglutinogen a. The presence of isoagglutinogen c in association with isoagglutinogens a and b has been demonstrated in the red cells of three members of group I. In an earlier investigation two members of this group were found whose red cells contained isoagglutinogens a and b, but not isoagglutinogen c. A fifth isoagglutinin (Q) was found in the serum of one member of group IV; it was quite distinct from agglutinins A, B, C, and D. The corresponding isoagglutinogen (q) was present in the red cells of another member of group IV. Neither this agglutinin nor this agglutinogen were found in any other blood in the series. This agglutinin (Q) was present in lower concentration than the others and therefore required a lower temperature for its demonstration. Its action occurred within one of the four accepted groups rather than between these groups, but in the quality and specificity of the agglutinin produced, it was in no way inferior to the others.

Leucocytic Picture in Catarrhal Jaundice (Cholangitis).—Ethel Thewlis and William S. Middleton (*American Journal of the Medical Sciences,* January, 1925) present this summary: Leucopenia is an almost constant blood finding in uncomplicated catarrhal cholangitis. In a certain percentage of cases it may precede the appearance of the jaundice. In cases followed long enough a definite postfebrile, reactive leucocytosis is remarked. The polymorphonuclear neutrophiles suffer more than any other white blood element in the primary depression. This disproportionate decrease of the neutrophiles leads to a relative lymphocytosis, but the actual number of these elements is decreased, as a rule. The large mononuclear cells alone appear to be constantly increased in catarrhal jaundice. In moderate cases a return to the normal numerical and differential counts occurs within two weeks. From a practical viewpoint these data should serve as important diagnostic criteria. Prognosis in catarrhal jaundice may be guided by the degree of the leucopenia and the trend of the leucocytic curve. The degree of leucocytic depression is frequently in direct ratio to the severity of the underlying condition. Furthermore, the lowering of resistance incident to a decrease in the leuoccytes in catarrhal cholangitis must impress the practitioner with the necessity for the protection of such persons from exposure to infectious disease, until a normal leucocytic level has been reëstablished.

Shortened Bleeding Time in Hemorrhagic Disorders.—P. Emile-Weil (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris,* July 10, 1924) points out that in a few cases of hepatic disease with hemorrhagic manifestations or of chronic hemorrhagic diathesis the bleeding time may be shortened instead of increased. Aside from these conditions a shortened bleeding time is met with only in myxedema and hypothyroid states. One of the author's cases was severe chronic hemorrhagic diathesis with purpura, bleeding gums and epistaxis so copious as to threaten life. Yet numerous incisions in the ears would not yield a drop of blood. Five hours later, however, they began to bleed and continued to do so for a long time, showing clearly the existence of a blood dyscrasia. The coagulation time was normal, but the clot did not retract. Another case was cerebral hemorrhage; the bleeding time is regulary increased in such cases, but in this patient it showed two and a half, one and two minutes. In a third case the patient had cardiorenal disease with azotemia, hemoptys and epistaxis. The bleeding time showed three and a ha one and a half and one minute. Variations of the bleedi time at different times in the same patient are even mo significant than the actual increase or decrease of bleedi time. They also show the importance of the associat vasomotor factor in the production or continuation of t hemorrhages.

Blood Platelets in Anemias and Acute Disease Their Number and Morphology.—G. J. Crawfo (*Lancet,* September 20, 1924) draws the following concl sions: A considerable diminution in the platelet count m occur in pernicious anemia, lymphatic leucemia, and purpu hemorrhagica, whereas an increase in these elements of t blood is observed in lymphadenoma and in myelogeno leucemia. In the cases of secondary anemia examin normal or slightly increased counts were obtained. Gener speaking, an increase of platelets would seem to be associat with a hyperactivity of the bone marrow, and vice ver suggesting that the platelet originates in this portion of t hemopoietic system. In one case examined, splenecto resulted in a considerable increase in the platelet cou An increased bleeding time is associated with a low platel count. No correlation could be made out between the blee ing time and the coagulation time.

Distribution of Phosphorus Compounds in the Blo in Tuberculosis.—K. Lucille McCluskey (*Journal of La oratory and Clinical Medicine,* March, 1925), because of t important rôle of phosphorus in the metabolism of t tubercle bacillus, studied the distribution of phosphorus co pounds in the cell and plasma, and attempted to ascert any tendencies toward progressive changes concomitant wi the various stages of tuberculosis. The results obtain showed the following: A disturbance of phosphorus meta olism in tuberculosis; a decrease in lecithin content of bo the cell and the plasma, with a simultaneous increase in ac soluble phosphorus, represents a grave prognosis, while t opposite indicates a favorable condition. The size of t red cell is decreased in tuberculosis, except in the first stag and the volume per cent. of cells is decidedly decreased the far advanced exudative type. The sum of the lecit and acid soluble fractions is equal to the total phosphor except in group I, terminal stage, in which the total pho phorus is greater than the sum of these two fractio This additional phosphorus fraction is confined to the c and represents a group not soluble in ether alcohol trichloracetic acid.

Uric Acid Levels in the Blood of Man and Animals. A. T. Weathers and H. C. Sweany (*Journal of Laborato and Clinical Medicine,* March, 1925) compare the new Fo and new Benedict methods for determining uric acid the blood of man. Most animals have a small amount uric acid in the blood as determined by these newer techni Very accurate determinations of uric acid can be made 0.5 to 1 c.c of blood. The normal level of uric acid shou be raised from 1 to 3 mm. to 1 to 4 mg. of uric acid 100 c.c. The uric acid in tuberculosis was found to about normal in all phases of the disease, with a tendency decrease as the disease became far advanced. The tw methods were found to yield the same results, and ea gave a fairly accurate recovery of uric acid added to huma and animal bloods. Polyphenols and aminoacids in quan ties double those found in normal bloods did not make appreciable error in uric acid determination by these metho

Leucocytic Phase of Hemoclastic Shock.—William Middleton (*Journal of Laboratory and Clinical Medici* March, 1925) reports observations on three cases in wh the control of whole milk was kept at 200 gm., but t quantity of the component elements was in each case divi by two. Casein, butterfat, and lactose were used in th experiments in the amounts found in 100 gm. of whole mil White cell counts were taken every twenty minutes a t the ingestion of the element to be tested over a period three hours. An alimentary leucocytosis did not follow t ingestion of whole milk. The time of the appearance the leucocytic depression was inconstant, as was also i degree. Three successive falls in the leucocyte curve we traced in each instance. Contrary to the results of Wid

sein showed a true shock response in only one of the two ses studied. The curves for whey, containing the other otein constituent of milk, were bizarre, and incapable of conciliation with their parent curves. Butterfat, on the ıer hand, showed a resemblance to the whole milk curves two of three cases. Lactose significantly conforms most sely of all the studied elements of milk to the basic whole lk curve. The occurrence of a typical reaction on the gestion of water in one case casts doubt on the significance the organic factor, protein or otherwise, in the causation the blood changes. The degree of leucocytic fall with reduced proportions of the elements of milk as comred with the basic curves of whole milk is surprising in ny instances. The author draws no conclusions from se few instances, but says that the indication is clear t a protein element is not essential for the production of noclastic shock in cases of catarrhal cholangitis.

Comparison of the Effects of X Ray and Dry Heat on ıtibody Formation.—James B. Murphy and Ernest ırm (*Journal of Experimental Medicine,* February, 1925) nfirm and extend the observations of Hektoen and others t x ray in large doses given before and during the imnizing process retards definitely the production of such ibodies as precipitins, bacterial agglutinins, and protec- antibodies, for rabbits receiving sufficient doses of x ray reduce the amount of their lymphoid tissue without nage to the bone marrow showed a definite reduction of se antibodies. The evidence pointing to the lymphoid ue as the manufacturer of antibodies is strengthened by experiments reported in which an animal's ability to m such bodies was greatly increased by the stimulation the lymphoid tissues by dry heat.

Allergic Irritability.—Anaphylaxis in the Guineapig as fected by the Inheritance. Paul A. Lewis and Dorothy omis (*Journal of Experimental Medicine,* March, 1925) nd that the regularity with which a series of guineapigs four different families reacted in classical anaphylaxis periments with horse serum as antigen varied from family family. The order, in the small series studied, happened follow the order of resistance to tuberculosis. They think t a difference in allergic irritability with reference to phylaxis, resting on the basis of family and hence of eritance, is at the least very strongly suggested by the ılts of the experiments described.

nfluence of the "Diaplyte" Antigen of Dreyer on berculosis of the Guineapig.—Jacques J. Bronfenbren- and Elmer L. Straub (*Journal of Experimental Medi-*, February, 1925) prepared a "diaplyte" antigen accord- to the method of Dreyer, and used guineapigs to test its apeutic value. The gross autopsy findings yielded no lence of differences between the condition of animals ted with antigen and the untreated controls. In fact, effect of treatment was to accelerate the fatal issue, er than to delay it.

ffect of High Fat Diets on the Content of Uric Acid Blood.—Victor John Harding, Kathleen Drew Allin, he Alfred Eagles, and H. B. Van Wyck (*Journal of ogical Chemistry,* February, 1925) observed that high diets producing a ketosis invariably raise the uric acid ent of the blood, and that often the rise in uric acid is mpanied by an increase in the nonprotein nitrogen h is not attributable to an augmentation of the blood . This uric acid increase may be brought down to its nal level by a carbohydrate or protein diet. The inse can be partly accounted for by a decreased blood me with a consequent decreased elimination. In fifty cent. of the cases, however, such an explanation would ar insufficent to account for the great increase in the d uric acid.

asma Lipoids in Experimental Anemia.—W. R. r (*Journal of Biological Chemistry,* February, 1925) d that the weights of total fatty acids, combined in ous forms and free, average about thirteen per cent. r in anemic animals than in the normals, and the total ponifiable matter (mainly cholesterol) about eight per higher in the anemics. The iodine values of the fatty average about thirteen per cent. higher in the anemic als. The high weight for fatty acids occurs only in ecithin and first two ester fractions; in the others the ıts are below the normal. The significance of the increase saturated acids is difficult to determine. Bloor states in ssing his results that the blood corpuscles have been found to take part in certain phases of fat metabolism, and it is possible that the diminished number of corpuscles in anemia is the cause of the phenomenon. However, the blood forming organs, such as the marrow of the long bones, are undoubtedly stimulated by the bleeding, and the suggestion that has been offered for the great increase in amount and degree of unsaturation of the blood lipoids, which is observed after repeated hemorrhages in rabbits, may apply here, i. e., the forcing out of the fat marrow by the blood forming red marrow. It is emphasized that the increase of unsaturated acids is the result and not the cause of the anemia.

Effect of Intravenous Administration of Sodium Citrate in Two Cases of Hemophilia.—Lee D. Cady and E. Lee Shrader (*Journal of Laboratory and Clinical Medicine,* June, 1924) noted certain definite symptoms in two cases of hemophilia if the sodium citrate was injected too rapidly; the only symptoms that were allowed to occur being subjective. At first after intravenous injections of sodium citrate there may be an increase in the clotting time for a few hours, but this is followed by a decrease. Repeated injections do not seem to have the beneficial effects of single injections. The platelets were diminished immediately after the injections, and slowly returned to normal. Intravenous administration of sodium citrate of hemophilic patients appears to be harmless and not contraindicated when not repeated too frequently.

Pernicious Anemia and Renal Insufficiency.—Ralph H. Major (*Bulletin of the Johns Hopkins Hospital,* December, 1924) found in a small series of pernicious anemia patients with a gastric anacidity, a high color index, a high volume index, and a typical clinical appearance, that the urine showed such a low excretion of chlorides as to suggest a retention. The patients were then given salol coated sodium chloride tablets in doses varying from six to twenty gm. a day. This produced no increase in the excretion of chlorides, and they had no evidence of renal disease, and two of the patients had no albuminuria. These findings suggest the possibility that the retention of chlorides in pernicious anemia is not due to renal disease, but bears some analogy to the retention seen in lobar pneumonia and in certain cases of intestinal obstruction.

Use of Desiccated Red Bone Marrow and Spleen in the Treatment of Anemia.—William Thalhimer (*Journal of Laboratory and Clinical Medicine,* November, 1924) gave practically all the patients treated with spleen marrow compound three five grain capsules a day. Of forty six patients with secondary anemia, forty-one showed an increase in the circulating erythrocytes and hemoglobin. In four patients with pernicious anemia the administration of the capsules caused a prompt decrease in both hemoglobin and circulating erythrocytes; therefore the preparation should not be used in this condition. One patient with Von Jaksch's anemia showed both a marked clinical improvement and an improved blood picture. In one patient with hemolytic icterus, whose spleen had been removed eleven months previously, hematopoiesis was stimulated by the preparation. Patients with pulmonary tuberculosis responded favorably to this treatment.

Tuberculous Cervical Lymph Glands.—J. M. Hanford (*Annals of Surgery,* December, 1924) offers the following conclusions to his preliminary report upon the subject. Operation is indicated in a large number of patients with tuberculous cervical lymph glands. It is impossible to make rules covering all the combinations of lesions and regions which may be seen in patients with more or less extensive involvement. An adaption of the main principles is worked out for every patient. Early removal of all tuberculous tissue is the ideal; but it must be tempered with an eye to the ultimate appearance of the neck and with safety to the patient and to the important structures. After time and conservative treatment have done their work, a later removal, if needed, is always worthy of consideration. The results with conservative treatment (including the simpler operations) are so good that only those radical operations are done which are relatively easy and devoid of nerve and vein damage. The more extensive operations are relatively safe in the submental, submaxillary, subangular, posterior auricular, suboccipital, lower deep cervical regions, and in that of the axillary glands. Damage to the nerve to the lower lip is surprisingly frequent in the submental and submaxillary regions. Damage to the accessory nerve is not infrequent in the subangular region.

In the subangular region early complete excision is recommended. In the subangular, deep mastoid, suboccipital, mid part of posterior superficial chain of glands, and in the lower deep cervical regions complete excision of the whole mass of disease is replaced by the safer but less ideal procedures as needed according to the lesions Operative procedures are but a part of the whole plan of treatment and may be indicated at any period, depending upon the general and the local conditions.

Injury and White Blood Cell in Inflammation.—H. A. Abramson (*American Journal of Medical Sciences,* May, 1924) offers a theory that one of the forces guiding the white blood cell to a point of injury followed by an inflammatory process may be the current of inquiry (demarcation current). With nonpolarizable electrodes under stated conditions, small lymphocytes migrate toward the anode which may apparently be compared to an injured tissue focus where inflammation has set up. Polymorphonuclear leucocytes under the same conditions do not consistently go toward one pole or the other. The probable cause of their failure is discussed. The speed of fifteen microns a minute manifested by small lymphocytes was the same whether freshly drawn blood cells were studied, or those taken from defibrinated blood kept on ice up to thirty hours. Little if any ameboid motion was observed during lymphocytic migration. Those tissues which respond most easily with the picture of inflammation to injury, should have the greatest currents of injury, thus correlating the view expressed with the pathological processes. The mechanical and chemical makeup of tissues is stressed as a deciding factor in ease of production of the picture of inflammation.

Reciprocal Relationship of Chlorides and Glucose in the Blood.—W. W. Herrick (*Journal of Laboratory and Clinical Medicine,* April, 1924) reports a fairly constant reciprocal relation between the concentration of glucose and the chlorides in the blood under the conditions of the ordinary glucose tolerance test in a fasting patient. The simplest and most attractive explanation offered for this behavior of the chlorides in the presence of increasing concentration of other crystalloids in the blood is that, in an attempt on the part of the body to maintain its fluids in osmotic balance, the chlorides are forced out. This might be by excretion or by redistribution, that is, by increased concentration in other tissues.

Tissue Resistance and the Cause of Permanent Acquired Immunity.—S. Nukada and T. Matsuzaki (*Journal of Experimental Medicine,* November, 1924) have demonstrated experimentally that the tissue cells of the hearts of typhoid immune animals are altered in such a way that their resisting power is increased specifically against toxic products of typhoid bacilli. The acquired increase of resisting power is specific. The authors maintain that permanent acquired immunity, at least in typhoid, instead of being principally caused by antibodies in the blood, is due rather to a lasting specific increase of resisting power acquired by the tissue cells against the toxic products of bacteria. This seems to hold true not only with typhoid, but also with other infectious diseases, in which one attack causes lasting immunity.

MALIGNANCY

Principles of Treatment in the Radiotherapeutics of Cancer.—Francis Hernaman-Johnson (*Lancet,* September 27, 1924) summarizes some fundamental principles and also his personal views, based upon what actually happens in the living subject, as follows:

1. The wave length most suitable for any given type of growth can be found only by clinical observation.

2. If an injury is inflicted by rays of a given wave length, the lesion may be cured or mitigated by rays of a widely different wave length.

3. Malignant tumors should be regarded from a dynamic and not from a static viewpoint. The microscope does not enable us to say that any two tumors are really alike.

4. The still healthy parts in the neighborhood of a tumor play a vital part in the success of any theraptutic measure.

5. When intensive dosage is used, the amount of radiation which is concentrated upon a tumor should not exceed the maximum consistent with the production of a healthy reaction in the surrounding tissues.

6. The socalled danger of a stimulating dose is a bogey. If the danger were real it would forbid the treatment by x rays of any but the earliest growths.

7. The intensive method should rarely be used to rend a case operable, and never as a prophylactic after operatio For this purpose, and as a palliative in hopeless cases, t small divided dose is alone suitable.

Gallstones and Cancer of the Gallbladder.—As a resu of his experimental study on animals, Archibald Leit (*British Medical Journal,* September 13, 1924) comes the conclusion that, in the human subject, gallstones a capable of causing cancer of the gallbladder. Freely a mitting that they do so in a comparatively small proporti of cases, it may be admitted that in some subjects there is natural resistance to carcinogenic agents, just as there is natural resistance to pathogenic organisms, and, learni from previous experiments that similar tumors may produced by wholly dissimilar agents, the carcinomata the gallbladder which are found in the absence of gallston may be accounted for as being due to some other cau agent or agents not yet identified.

Fibroid Gumma (Juxtaarticular Nodules of Lutz-Jea selme).—Sigmund S. Greenbaum (*Journal of Laborato and Clinical Medicine,* March, 1925). Because of the rec observation of a typical example in a syphilitic, who h a primary lesion eleven years previously and who presen symmetrically on the elbows, on the right knee and the left palm, very hard hypodermic and dermohypoderm nodules of six to eight years' duration, and because of t apparent rarity and the lack of uniformity regarding th etiological significance, a clinical review of this combin syphilitic fibrogummatous lesion and its relation to t fibromata and the juxtaarticular nodules, so common the orient and tropical countries, is presented by Greenbau The case is a typical example of a condition observed Lutz in 1891 and later by Jeanselme.

Resistance to Spontaneous Mouse Cancer Induc by Injections of Oleic Acid.—Waro Nakahara (*Jour of Experimental Medicine,* March, 1925) used oleic a in this work because the range of doses effective agai transplanted cancer is wider than in the other unsatura fatty acids which have been tested. The object of work was to determine first the effect of oleic acid inj tions on the frequency of recurrence after operative moval of spontaneous mouse cancer, and second, the eff on the incidence of takes of autoplastic cancer grafts. effect of oleic acid injections on the postoperative clin course was a reduction of local recurrences, of new prim tumors, of metastases, and of total recurrence of disea Sixty-two per cent. of the treated animals showed comp freedom from the tumors, as against twelve per cent. the controls. The average postoperative longevity in treated mice was 147 days, which was forty-nine d longer than in the control series. It therefore seems t the resistance of mice to spontaneous neoplastic disea can be increased by means of oleic acid.

Nature of Cancer.—G. W. Crile (*Annals of Surg* September, 1924), on the basis that the processes of division in cancer are analogous to the processes of division in fertilized cells, reports certain biophysical searches and points out certain pertinent facts tending show that cancer falls within the domain of electrochem or bipolar theory which applies to normal living proces Various suggestive analogies between cancer and pyog infections are drawn, to aid in forming the basis of a ment. Up to the present time, the successful findings these researches suggest that the whole story of ca may ultimately be derived from conductivity and capa measurements. The author states that the theory ha least this advantage, that it has been formulated developed on the basis of exact mathematical formulas physical laws and in consequence can the more readil disproved if not true, and if true can be the more ea defended.

Mikulicz Operation for Cancer of Sigmoid.—C. Mayo and W. Walters (*Surgery, Gynecology and Obstet* July, 2924) reprint W. J. Mayo's description of this op tion, adding certain modifications of their own, particul in regard to the objection that in the original opera the bowel was allowed to heal in the wound before be opened. It has been their practice in the clinic to ren the portion of the bowel containing the tumor at primary operation whenever it could not be elevated ab the incision, or its circulation was so seriously interfe with that gangrene was to be expected, as it was no

certain of these cases that septic thrombi progressed eeply, resulting in peritonitis. Also, if the lower fragment very short, the growth is cut away at once. The two nds of the bowel are then clamped, the clamp on the ower part being used as a temporary elevator, and left a place until it comes away itself, by which time the ower fragment has attached itself with sufficient strength o remain in the lower angle of the wound. In a number f instances in which the cancer was very low in the igmoid, the entire rectum was loosened up to the levator ni muscle, and by the forceps method, the upper end of ne rectum was maintained in position, the peritoneum of ne lower pelvis being obliterated by sutures, and a pack f vaseline iodoform gauze introduced about the forceps. he space in the hollow of the sacrum was drained by right lateral stab wound. An opening can be made in ne proximal fragment above the clamp at any time to elieve the pressure of gas, and so forth. Ultimate closure f the sigmoid ends is made extraperitoneally, or if necesary, by the tube method of Balfour.

Carcinoma of the Colon.—C. H. Peck (*Annals of Surery,* September, 1924) believes that cancer of the colon xcluding the rectum offers a relatively high rate of perability, and a percentage of radical cures which comares favorably with that of malignant disease in other rgans. Growths of the cecum, and right colon, including he right part of the transverse colon, are suitable for a ne stage resection with immediate anastomosis by suture. he operative mortality should be relatively low. Left olon growths are more safely resected by the two stage Mikulicz method.

Multiple Foci in Cancer of Colon.—R. T. Miller, Jr. *Annals of Surgery,* September, 1924) presents ample evience to show that in a practical sense we must recognize hat cancer of the colon may occur as multiple primary esions, that an entirely similar picture may be produced y tumors which developed secondarily, and that polyposis f the colon has a tendency to malignant degeneration.

Anorectal Cancer.—S. G. Gant (*American Journal of Surgery,* September, 1924) pleads for the substitution of erineal and vaginal extirpation for Kraske's and the ombined operations with permanent colostomy in the reatment of anorectal cancer, on the following grounds:

Benefits derived from sacral excision are more than ounterbalanced by its many disadvantages, since Kraske's peration is prolonged and difficult, is accompanied by free emorrhage, induces decisive immediate and subsequent hock, is responsible for a higher mortality than perineal nd vaginal excision; lung and kidney complications from ther are frequent; the patient, if he survives, is compelled o remain in the hospital for weeks owing to the extent nd nature of the wound, which often becomes infected nd breaks down partially or throughout; the removal of one necessitates a sacral anus that prevents the patient sing the toilet normally, destroys pelvic support resulting n slight or extensive sigmoid al procidentia, injures nerves ontrolling rectovesical musculature causing fecal incontience, is sometimes followed by necrosis, leaving of irriating bone spicule, a hypersensitive sacrum or painful scar nd is responsible for a noncontrollable sacral anus that requently requires dilating to prevent the opening from ecoming strictured through contraction of surrounding car tissue.

The benefits said to accrue from the combined operation nethod are more than counterbalanced by the high morality of the procedure, which is four times that of perineal nd vaginal excision, the dangerous complications that ccompany or follow it and the permanent artificial anus hat is left to the disgust of the patient.

Briefly enumerated, other serious disadvantages of the ombined method are: The operation is accompanied by evere shock; it is unsuited to obese and debilitated atients; it requires twice as much time to perform as erineal or vaginal extirpation; extensive manipulation of bdominal viscera in search for diseased glands and organs s occasionally responsible for paralytic ileus; ureters, bladder and iliac vessels may be traumatized or seriously njured; death from hernia has ensued where the gut xtruded through an aperture in the closed pelvic periioneum; local recurrence is as frequent as following erineal or vaginal extirpation; and heart, lung, kidney nd bladder complications resulting in death or prolonged onvalescence are common.

Experimental Production of Mammary Carcinoma in Rabbits.—Katsusaburo Yamagiwa and Koschiro Murayama (*Journal of Cancer Research,* April, 1924) have produced twenty-three cases of cancroid and adenocancroid resembling that observed in man, in the past five years during the course of experiments on 188 animals. The epitheliomata were produced by injection of liquid tar extract, pure tar, mixture of tar and lanolin, liquid paraffin containing tar, olive oil, or liquid paraffin, in the doses of from 0.3 to 0.5 c.c., into the mammary glands; this injection was made once or twice a month. Animals dying after one or two injections were excluded. The development of epithelioma in 12.23 per cent. of the animals injected is considered a high average, especially taking into consideration the fact that spontaneous mammary carcinoma seems to be unusual.

Fibroma of Abdominal Wall.—M. J. Stewart and T. B. Mouat (*British Journal of Surgery,* October, 1924) consider this complication from all angles, and from a series of cases find that fibroma of the abdonimal wall is a simple fibrous tissue tumour arising in the musculoaponeurotic structures of the anterior abdominal wall, especially below the level of the umbilicus, and tending to infiltrate the muscle in which it lies. It is met with in women who have borne children to the extent of eighty per cent. of the reported cases, and it occasionally occurs in the scars of old hernial and other abdominal operation wounds. In other cases there is a history of local injury. A traumatic theory of origin seems reasonable, and the physiological trauma of labor would appear to be of special importance. The infrequency of the condition points to the presence of some additional unknown factor, which, in the absence of more accurate knowledge, may be termed individual predisposition. A peculiar change in the striped muscle fibres enclosed in the growth is described. It appears to be a process of dedifferentiation and results in the formation of multinucleated plasmodial masses resembling foreign body giant cells. Fibromata of the abdominal wall are usually of slow growth in the earlier stages, but with the advent of mucoid or myxomatous change a rapid increase in size may occur. They do not undergo metastasis nor do they endanger life, but there is no evidence that they ever disappear spontaneously. Treatment should be early and complete removal, with resection of a margin of healthy tissue wherever muscle, fascia, or peritoneum is invaded by or adherent to the growth. Recurrence means incomplete resection and demands a more radical operation. There is no evidence that sarcomatous metamorphosis ever occurs.

Pseudomyxoma Peritonei.—E. Ries (*Surgery, Gynecology and Obstetrics,* November, 1924) reports that pseudomyxoma peritonei is a secondary condition due to the escape of gelatinous material from a primary tumor. This tumor arises in the ovaries or in the appendix or both or rarely in other organs. The ovarian tumors are always pseudomucinous kystomata in their entirety or at least partially. The appendices from which pseudomyxoma peritonei starts are always more or less cystic, often show diverticula, and may contain papillomatous tumors. The operative treatment is successful in proportion to the completeness of removal of the original tumors and the pseudomyxoma peritonei. Every case of pseudomyxoma peritonei, especially in the female, requires investigation of the appendix and its removal. The chemistry of the gelatinous masses deserves further study with proper attention to the sources of the colloid material. The coexistence of ovarian tumor with appendiceal cyst in pseudomyxoma peritonei is a frequent finding. There is at present no evidence of anything more than accidental coexistence of the two conditions.

Fibrosarcoma of the Transverse Colon.—F. W. Rankin and J. C. Crager (*Surgery, Gynecology and Obstetrics,* December, 1924) assert that the mortality in all types of operation which formerly was as high as fifty per cent., but which under modern technique has been reduced to approximately ten per cent., will not be found to be decreased with a Mikulicz operation unless some other procedure in addition is adopted. We have tried the application of two stages of this procedure in one, doing the operation between clamps, removing the bowel segment with a cautery and leaving the bowel at the site of operation obstructed for a number of days. Supplementing this type of retention with an ileostomy about sixteen inches from the ileocecal coil, is a valuable adjunct toward reducing the untoward postoperative symptoms by draining the toxic products of the small bowel. The steps of the operation are simple.

Medicolegal Notes.

LIABILITY FOR TORTIOUS ACTS OF EMPLOYEE OF STATE UNIVERSITY'S INFIRMARY—IMMUNITY OF UNIVERSITY

The California District Court of Appeal, First District, holds, Davie v. Board of Regents, University of California, *227* Pac., 243, (rehearing denied by Supreme Court), that the maintenance by a state university, of an infirmary for the exclusive use of its students, conducted by it for the sole purpose of safeguarding and protecting the health of the student body, is a governmental function, and the university is not liable for the tortious acts of its employees. Being in no sense an organization for profit, the imposition of a small fee did not convert the governmental function into a proprietary one. The court says: "The reason for the rule that the policy of the law denies liability of a state or municipality for negligence of its servants and physicians is that such an activity being a governmental agency, to permit such liability would result in enormous public burdens."

The university had the power to establish and maintain the infirmary under article 9, §9, of the state Constitution, providing that the "corporation shall also have all the powers necessary or convenient for the effective administration of its trust."

The same court holds, however, Davie v. Regents of University of California et al, *227* Pac., 247, that this immunity does not extend to and cover a physician acting in the course of his employment as an agent of the university. The court says: "The principle which protects the regents is inapplicable to him. Where wrongs are done to individuals by those who are the servants of the government those injured are not remedyless, as such servants or employees may be sued the same as other persons for torts which they have committed."

QUESTION OF MORAL TURPITUDE IN PRESCRIBING NARCOTICS

The Tennessee Supreme Court holds, State Board of Medical Examiners v. Friedman, 263 S. W., 75, that, although a license to practice medicine once issued does not constitute a binding and valid contract with the state, or confer upon the holder of the license a vested right, the right to practice medicine is a property right, of which one cannot be illegally deprived.

It is held that the state board of medical examiners cannot revoke a physician's license on the ground that he had been convicted of an offense involving "moral turpitude" within the meaning of section 16, subsection 6, of Tennessee Acts 1919, c. 105, solely because he had been convicted of a violation of the Harrison Anti-Narcotic Act, although violation of the act constitutes a felony, since the mere violation of a revenue act may not in and of itself constitute "moral turpitude." By chapter 105 of the Acts of 1919 it is made pe missible for any physician in the state of Tennessee to pr scribe as much as eight grains of morphine per day to a one patient. It cannot, therefore, be said that prescribi morphine in considerable quantities is an act involving "mor turpitude," or even an illegal act in that state.

The court, however, thought it "is conceivable th there might be a conviction under the Harrison Act whic would show that the convicted physician had been guilty acts involving 'moral turpitude' when he violated the feder statute in question.

"Thus, suppose it should be shown that the convicte physician was in fact a mere drug peddler, preying on t necessities of the unfortunate class known as 'drug addict The record of the conviction, in such a case, might indica a high degree of 'moral turpitude.'"

On behalf of the state board it was claimed that the pre ent case was one of this nature. The original bill in the su was filed to review the action of the state board of medic examiners in revoking complainant's license to practice med cine, and to compel his reinstatement as a practitioner. T board demurred to the bill on various grounds, and the cha cellor overruled the demurrer. The board stood on the demurrer, and decree was entered for the complainant, fro which the board appealed. The Supreme Court is of opini that cases of this nature should not be decided on demurre and remanded the case for answer and proof on the questi of "moral turpitude," in accordance with the principles state

"DISCRETION" OF EXAMINING BOARDS IN LICENSING APPLICANTS

The Michigan Supreme Court holds, Wilson v. Michig State Board of Registration in Medicine, 199 N. W., 6 that the exercise of sound discretion on the facts submitt to them, which is vested in such a board as defendant, do not include the exercise of arbitrary will. In a mandam suit to compel the issue of a certificate of registration plaintiff under Comp. Laws 1915, §67226, the court fou that the defendant, in its answer to an order to show cau why writ should not be issue, "sets up no fact or set of fac upon which it exercised such discretion, if it did so, and its answer gives no grounds or reason for such refusa but states only legal conclusions without any facts up which to base them. The court said: "If such an answer sufficient to our order to show cause, then the actions such boards possessed of discretionary power are immu from judicial inquiry. All that they would be required say is that they have used their discretion without givi any reason for their decision or state any facts which the basis of their finding; they could register or refuse register without giving any reason at all for their acti they could at will register one applicant and reject anoth possessed of the same qualifications."

CAUSE OF INJURY FOR JURY WHERE EXPERT MEDICAL TESTIMONY CONFLICTS

The Nebraska Supreme Court holds, Culver v. Uni Pacific R. R. Co., 199 N. W., 794, that where the opinion medical experts as to the cause which has produced a lesi of the spinal cord, causing partial paralysis, is in decid conflict, the question whether the injury to the cord was t result of external accident or was the result of disease one for the jury, there being sufficient evidence to supp a verdict based upon either theory.

EXPERT OPINION AS TO CONSEQUENCES OF INJURY BASED CONJECTURE HELD INADMISSIBLE

The Illinois Appellate Court holds, O'Donnell v. Snyd 231 Ill. App., 581, that it was error to permit medical e pert witnesses for the plaintiff in a personal injury actio testify as to probable and possible results from the inju where their testimony fell far short of the reasonable ce tainty as to future consequences required by law, and w apparently based on conjecture.

CHIROPRACTORS MUST HAVE LICENSE UNDER PENNSYLVAN STATUTE

The Pennsylvania Superior Court holds, Commonweal v. Martindell, 82 Pa. Superior Ct., 417, that a person wh practises chiropractics practises medicine and surgery defined in the Act of June 3, 1911, P. L., 639, as amend by the Act of April 20, 1921, P. L., 158, and is proper convicted of a violation of the statute if he practises h profession without obtaining a license. A contention th he made no diagnosis was rejected as a contradiction terms, since he, like others, must begin by a diagnosis.

The Problem Method of Medical Teaching

Its Advantages and Objections

A. D. BUSH, M.D.

Emory University, Georgia

At no time does one concentrate so thoroughly on the available data as when endeavoring to attain the solution of an absorbing problem; and at no time does one so take cognizance of pertinent facts as when equipping oneself to meet a definite situation. For example, consider the orthopedic surgeon who is faced with the task of correcting a deformity different in nature from any other he has heretofore encountered. Carefully and minutely he studies the case before him, noting the various stresses that have led up to, or that now maintain, the present strain and deformity; studiedly he compares the abnormal condition with the structures forming the normal; not unlikely he visits the nearest anatomical laboratory and painstakingly dissects ligament, muscle, and bone that he may be adequately sure what tensions at this point, or what relaxations from that area, will produce a given effect. He may next go into the pathological museum to study whatever related sequences of malformation have come to the attention of that department; he may confer with the physiologist regarding the mechanics of normal functioning of the part being studied, and as to what might be expected from partial restorations of deformed structures. He assiduously consults the literature of anatomy, pathology, and orthopedics, seeking to ascertain all correlated information. And all the time foremost in mind he has the problem of suitable correction of a particular deformity; that is the central idea around which is gathered all the other informational data; that is the uncertainty which all these other facts unite to illusine.

A similar method is pursued by the careful surgeon who aims to utilize the advantages offered by laboratory, museum and library before undertaking a new and difficult operation. In like manner, the internist avails himself of all avenues of preparation at his disposal, the better to meet the trying situations that may be confronting him.

If the clinical men, and the men out in practice, find this method the one yielding the best results, why would not a similar method yield best results when used with the student? In what other way could the teacher so arouse enthusiasm, or so maintain the student's interest, as by assigning a clinical problem whose solution required a careful linking up of cognate fundamental facts? And in what other way could those fundamental facts be so sharply impressed on the student's mind as when made a living part in the solution of a definite clinical problem?

As we in the United States all painfully know, teachers as well as practitioners (though perhaps with not as keen a realization), the present method of medical teaching consists in pouring into the mind of the student a tremendous conglomerate of uncorrelated, unapplied facts, especially in the socalled fundamental courses. Here in America we all contend that these foundation studies are absolutely essential to an adequate apprehension of the meaning of the clinical phenomena the student will encounter later; in fact, that he cannot possibly understand the meaning and bearing of those clinical phenomena unless he has had first an extensive and thorough grounding in the socalled preclinical subjects. On the other hand, the European is said to think that much of the time spent on thus aggregating facts uncorrelated with definite applications is, in reality, time wasted; that at best the student can retain but a relatively small part of all set forth, by the American plan, during the first two years, especially since its concrete relationship to medicine is not emphasized by clinical contact. He feels that the student, when burdened with such a heterogeneous mass of unsystematized data, is not able to handle his clinical problems wisely. So strong may be his conviction as to cause him to go to the other extreme and introduce his students to clinical problems when there exists practically no foundation work whatever. Such method we do not hesitate to criticize rather severely; but, on the other hand, have we deliberated carefully as to what justification the European may have for his criticism? Certainly, we are not satisfied with our present method of teaching medical students. The clinical men are sure something is radically wrong with the presentation in the preclinical years; the preclinical men are furtively restless, though much inclined to continue reservedly dignified; the students are growing resentful though discreetly inarticulate—except among themselves; abroad among the laity there is a smouldering questioning. In the face of all this it would seem as if

Copyright, 1925, by A. R. Elliott Publishing Company.

something might be done to weld together the advantageous points of both American and Continental systems while largely avoiding the demerits of each; it would seem that some plan might be evolved that would train the student in a closely coordinated manner, and that would keep him keyed up all the time with that enthusiastic interest that serves mightily to fix facts deeply in memory. The problem method, which is herewith submitted, might well be such a plan.

OUTLINE OF METHOD

In the problem method of teaching medicine the student is taken first to the clinic where he is shown a fairly typical case. To the student, or class, the instructor carefully points out the several leading manifestations of that particular disease entity, emphasizing over and over again what are the principal points to recognize in the diagnosis, and reiterating that each point demands a logical explanation from the realms of anatomy, physiology, and pathology; but what this explanation is, the clinical instructor refrains from discussing, as its ascertainment constitutes the very essence of the student's problem.

At the close of the clinical period, the instructor tells his class they are to proceed thence to the department of anatomy there to learn whatever in that department pertains to the clinical subject discussed; from there they are to proceed to the department of physiology (if in fact the departments of anatomy and physiology have not by that time become closely coordinated and amalgamated) there to learn what may be the functional significance of the structures involved; from there they go to the department of pathology-bacteriology to study what alterations from normal structure and functioning this particular disease entity may probably produce. All the time they will endeavor to learn the significance of many facts in their relation to a particular fact; will seek to ascertain the fundamental conditions that help to explain the troubles assailing suffering humanity; they will have an exceedingly definite goal toward which the several investigations being undertaken correlatively point. They will gather pertinent data around a central object; they will be afire with enthusiasm to learn whatever may help to enlighten.

Having thus received from the several fundamental departments such information as can be quarried, the class returns to its clinical instructor. The instructor endeavors to have ready at this time both the former patient and also a new one manifesting similar symptoms and stages as were beheld at first. One by one he recalls the several manifestations, and concerning each one he closely questions the class, drawing from the students such explanations of those manifestations as have been learned from the fundamental departments. Next, he outlines a suitable mode of treatment, shows the class the case or cases that have had such treatment, and then turns them over to a representative of the department of pharmacology and therapeutics for an adequate explanation of the rationale underlying the suggested treatment. (This cooperative teaching by groups is another desirable feature of this plan.) Finally, the class is provided with an extensive reference list to the periodical literature covering the several phases of this particular illness, and told to report at an early date at the seminar for a searching quiz and discussion. (Attending this seminar, in suitable sections, are also those members of the faculty who have cooperated thus far in the teaching; as well as others who may be interested.) Then, having completed this problem satisfactorily, the worthy members of the class are immediately assigned another similar problem—the next one in a carefully graded series, a series that ultimately (in four years, surely) will have covered as much ground as is now covered by the routine schedule.

"Impossible" say some, in consternation. Far from impossible; the method is largely and primarily a matter of administration, coupled, of course, with hearty faculty cooperation. Naturally, the administration of this method requires extensive planning and tactful persuading; while the faculty cooperation necessitates a preliminary deep conviction that the fundamental obligation of the instructor is to prepare the students to become increasingly proficient practitioners of medicine.

But before proceeding further with the argument let us now present a concrete illustration of the method, and, inasmuch as the graded course proceeds from the relatively simple to the relatively complex, we may as well use for a type some heart affection, say auricular fibrillation complicated with aortic leakage.

METHOD ILLUSTRATED

The class gathers in the clinic where the instructor proceeds to point out the leading manifestations of the disease complex, dwells on the important subjective symptoms and the associated objective phenomena, and in a general way indicates the many points essential to glean from the domains of anatomy, physiology and pathology before a correct diagnosis can be made or suitable treatment be attempted; with this preliminary introduction he starts the class on its investigation. Having first obtained from examination of a fellow student a more or less cursory notion of the surface findings in the cardiac region, the members of the class proceed to a painstaking dissection of the correlated area on the cadaver, making a thorough study of the heart's position, relations, coverings, orifices, structure, lining, valves, etc. Then the microscopic appearance of each part is carefully scrutinized. Next the function of the heart as a whole, then of each separate chamber, valve, bundle, and covering is investigated in whatever way the resources of the laboratory of physiology permit; at this time, however, special attention is given to the problem of conduction along the A-V bundle, and to the sundry phenomena produced by alterations in the relative efficiency of valve action.

From the laboratory of physiology the class proceeds to that of pathology, there to make an intensive study of those heart specimens that show minute and gross lesions, in both early and advanced stages, of cases similar to that displayed in the clinic. Any check work that bacteriology can offer will also be studied.

Then, having gathered up in this way all the fundamental data explanatory of the various manifestations of the disease, the students, with attuned and appreciative minds, return to the clinical instructor for further conferences. Again he rehearses the various symptoms, and receives from the mem-

bers of the class keen, intelligent explanations of those symptoms. He is now ready to suggest approved courses of treatment, which he does briefly or turns the class over to the pharmacology therapeutics department for investigation and rational explanation of why this or that medication is logically indicated as likely to assist nature in the curative process. Finally, literature references are given; and the class soon meets the faculty group for a seminar discussion of the leading points involved.

A similar routine may be followed in the clinic caring for fractures, which would involve the study of bones, joints, muscles, and ligaments, under normal and under fracture conditions; or in any of the clinics that look after internal diseases; care being taken that the localized disorders are studied before the disorders of widespread manifestations; or in any of the clinics connected with the various specialties. Each and all of them can readily be adjusted to this method of presentation; some will take more time than others, now in this laboratory and now in that one, but all are adaptable.

ADVANTAGES OF METHOD

The problem method of teaching medicine unifies the courses as no other plan yet tried. The teachers are brought more closely together in the work of cooperative instruction, and thus more nearly attain mutual understanding; but better still, perhaps, is the fact that the student remains in contact with the laboratories throughout his entire four years; he learns thereby not to make snap diagnoses but to put the uncertain to the rational test of experiment and consultation. Associated with each condition studied there is given the opportunity to learn what normal structure and function underlie that trouble, and what abnormality of structure or function induces the morbid condition or is induced by it. Abnormalities of structure, and aberrancies of function, are studied as well rounded entities, not as disparate fractions.

OBJECTIONS TO METHOD

But there are some objections to the adoption of this method of teaching and some formidable difficulties standing before it.

The first objection that will come to mind is that of administration. How would it be possible to arrange a graded course so that all fields of medicine would be covered adequately? This is largely a matter of office study and planning. It would require hearty cooperation from all members of the college faculty; and it assumes the facilities of a large clinic, such as the higher grade schools command. With these two factors assured, the administration would not be difficult.

But would it be possible to give laboratory instruction to all four classes throughout the college year? Certainly; the work would be so planned that no two classes would be assigned to the same laboratory at the same time, but would report for work at definite periods in close orderly sequence. The work would all be planned and scheduled beforehand, only such departures from the schedule being allowed as were necessitated by the exigencies of the clinic; in large cities, however, there are unhappily enough clinically typical cases appearing so that a dearth of illustrative material would be exceptional. The occasional could be studied when and as it appeared.

For purpose of discussion, say that a student's aggregate time spent in the laboratory of anatomy amounted to six hours a week throughout his course; his total time would be about the same as under the present system. This would allow him six hours a week for his other laboratories, six hours a week for his clinics, six hours a week for his special assigned readings and seminars, and six hours a week extra for makeup work, special investigations, additional clinics and conferences. (Many clinics, especially in the later years, would require additional work in pathology-bacteriology, but not in anatomy.) By rotating the classes in regular sequence the laboratories would be fully busy at least four days a week throughout the college year; this would probably necessitate an augmented laboratory force. There would be a marked diminution in didactic lectures in all departments; but an increase in conferences and seminars; and a quickening of interdepartmental cooperation, courtesy, and responsibility.

COOPERATION NECESSARY

But would a faculty agree to work together thus in groups? Especially, would the preclinical men be willing to thus subordinate their departments to a subserving of the clinical instruction? It is well known how jealous teachers can be of their real or assumed prerogatives, how conservative many preclinical men are in their pedagogy, and how many rigid formalists there are in the teaching profession. Yet when we call to mind that ninety-eight per cent. or more of our medical students are training to become practitioners of medicine, and that our bounden duty to them, as well as to society, is to make them as proficient as possible in their chosen vocation, it behooves us to adapt both ourselves and our methods so as to ensure to the fullest extent possible the maximal attainment of the ends sought. Those who are unable to adjust their minds in conformity to the welfare of both the student and society are out of joint with the times and with their environment. If they are unable to attain to an adjustment, they should be gently persuaded to adopt some pursuit more in harmony with their particularistic temperament.

There remains the problem of the two year school, and of the four year school situated in a city too small to afford a varied clinic; how could they adjust themselves to this plan? They couldn't very well; but doesn't the burden of responsibility rest with the school rather than on the plan? Has either the two year school, or the school with inadequate facilities, either an economic or pedagogic justification for continued existence?

CONCLUSION

The problem method of teaching medicine is an attempt to provide the student with a logical correlation of his work; to keep constantly before him throughout his entire course the ideal of service to the welfare of his patient; to inspire him with concentration of thought and effort; to unify the teaching, and to harmonize the teachers. It will stimulate development of the true research spirit, and will tend to make our physicians more thoughtful and scientific.

Does Tissue Fibrinogen Shorten the Clotting Time of Blood When Taken Internally?*

W. M. BILLING and A. P. MATHEWS
Cincinnati, Ohio

The discovery of a means of shortening the clotting time of blood by the oral ingestion of some substance might place in the hands of physicians a valuable means of controlling hemorrhage. The discovery, therefore, announced by C. A. Mills and his coworkers (3), that tissue fibrinogen of Wooldridge had this power, has attracted great interest, and also much scepticism, since the rapid absorption from the intestine of such a coarse colloid, especially one destroyed by the intestinal enzymes, seems unlikely. It seemed desirable to test out this action in more individuals and to try certain controls which were omitted by Mills owing to their not seeming necessary. The present paper contains results completely confirming the findings of Mills and his colleagues.

It will be recalled that tissue fibrinogen is the protein constituent of tissues which has the power of clotting blood, and also fibrinogen solutions when these contain calcium. It was isolated and named by Wooldridge in 1885. It is one of the two thromboplastic substances found in juice from injured tissues, the other substance being the phospholipin, cephalin, isolated by Bordet and Howell and identified by the latter.

These two thromboplastic agents have been shown by Mills (1) and by Mills and Mathews (7) to have quite different actions. Mills and his coworkers (1) found that tissue fibrinogen clotted blood by making a direct union with blood fibrinogen probably through calcium, the fibrin formed by it being tissue fibrinogen—calcium—blood fibrinogen. Tissue fibrinogen is part of the structural proteins of the cells, and it is this union which anchors the clotted blood to the injured tissue. Mills and Mathews showed that this clotting does not depend on thrombin or prothrombin, since tissue fibrinogen will clot blood in the entire absence of both thrombin and prothrombin; and no thrombin is produced in this clotting.

The other thromboplastic substance in tissue juice, namely cephalin, it will be recalled, converts prothrombin (or serozyme) to thrombin, probably by uniting with the prothrombin through calcium (Bordet's explanation). The thrombin thus formed clots blood presumably by direct union with fibrinogen, thus making thrombin fibrin.

There are then two distinct mechanisms of blood clotting of which the older is the tissue fibrinogen clotting.

It is known that tissue fibrinogen will clot blood intravascularly with great speed if a little of it is abruptly injected; but Mills and his coworkers found that any amount of it could be injected subcutaneously or intraperitoneally in animals without danger and with the effect of shortening the clotting time about one half. Thrombin, however, rapidly loses its power of causing intravascular clotting and it in no way effects the clotting time when injected subcutaneously, while it is stated that intravenous injection of cephalin will shorten clotting time. Yet subcutaneous or intraperitoneal injections of cephalin have no action.

But the most surprising discovery was made by Mills, Nakayama, Dorst and Mynchenberg (3) that tissue fibrinogen, although it is so coarse a colloid that it will not filter through a fine filter paper, yet when five c.c. of a one and one half per cent. solution are taken by mouth on an empty stomach in iced water, so that it quickly enters the empty duodenum, it is absorbed so quickly that in from fifteen to thirty minutes the clotting time of the blood may be reduced even fifty per cent. and more. Inasmuch as the in vitro action of tissue fibrinogen is rapidly destroyed by both pepsin and trypsin (4) this rapid intestinal absorption is so surprising as to have aroused many expressions of incredulity. The criticism has been made of Mills's results that they were due to the salt solution injected or to the iced water.

L. W.	172	2.25	1 50	2.17	— 3.5%
Average effect (reduction)					3.9%

In view of the great clinical value and theoretical interest of these observations it seemed wise to confirm them, and at the same time to try certain controls such as the action on clotting of salt solution when injected subcutaneously and also of ice water taken by mouth, although it seemed highly improbable that these procedures would have any effect on the clotting time of the blood.

In all the following experiments on a dozen or twenty normal adults, the clotting time was determined by Mills's simple but reliable clinical method, a method which gives very uniform results.

Subcutaneous injection.—We first tried the effect of the subcutaneous injection of one and five tenths c.c. of a physiological salt solution nine tenths per cent. in the deltoid muscle of the arm of ten healthy adults. Table I shows that this procedure produced no noticeable change in the clotting time of the blood drawn about one and one half hours after the injection. The changes recorded are within the limits of the usual experimental error of the method except possibly two, in which changes of sixteen to

hirteen per cent. were recorded but in opposite directions. Injection was made between 10:25 and 10:52 a. m. about three hours after breakfast. The slight reduction of three and nine tenths per cent. n the average is without significance.

We then tested similarly the action of tissue fibrinogen, on the same persons.

That tissue fibrinogen has a strong coagulating action under similar conditions is shown in Table II. The subcutaneous injection of twenty-two and one half mgs. of tissue fibrinogen[1] in one and one half c.c. of physiological salt solution produced in one to two hours quite uniformly a marked reduction in clotting time, the average being twenty-five per cent. reduction. In two cases eight and ten per cent. increases in clotting time were observed, one hour and nineteen minutes and one hour and thirty-two minutes respectively after the injection, but a test one half hour later showed that in these individuals the absorption had probably been slow as the clotting time was found to be reduced on this later test. The amount injected, one and one half c.c., is the minimum dose recommended by Mills, who advocates one c.c. for seventy-five pounds weight. The injections were given to the same subjects as the salt injections n Table I, and on the same day, three hours after unch. The results leave no doubt of the efficacy of small doses of tissue fibrinogen in lowering clotting time after subcutaneous injection.

Oral ingestion.—We then tried the effect of oral administration, first trying a control experiment on he effect of drinking ice water on the clotting time.

Table III. shows that drinking ice water (eight ounces) at 11:30 a. m. when the stomach was presumably empty did not affect clotting time in six healthy adults.

We now proceeded to test the action of oral ingestion of tissue fibrinogen in the same individuals.

In these experiments the minimum dose of a suspension of tissue fibrinogen was used. Three c.c. of suspension containing fifteen mgs. tissue fibrinogen per c.c. were administered in eight ounces of iced water. The experiments were performed at about 1:30 a. m. and in all cases at least three hours after the ingestion of food. The clotting times were determined immediately before and fifteen minutes after the administration of tissue fibrinogen. It will be seen by an inspection of Table IV that small doses of tissue fibrinogen, administered by mouth, together with a little iced water given to delay tryptic

digestion, result in a marked lowering of the clotting time of blood, the average reduction observed here being forty-eight per cent.

In the case of C. P. it may be noted that before ingestion of the tissue fibrinogen the clotting time is somewhat longer than usual. This person was at the time suffering from epistaxis, which had lasted ten days or more. The hemorrhage ceased one hour after the administration of tissue fibrinogen. It recurred in eight hours, lasting until the next morning, when seventy-five mgs. (five c.c. suspension) were administered by mouth, the hemorrhage ceased and no further trouble was experienced.

The fact observed by Mills that the clotting time of the blood can be so quickly affected by tissue fibrinogen taken by mouth, an observation which we have found confirmed in every experiment we have tried, provided only that the substance gets promptly

[1]The tissue fibrinogen used in these experiments was prepared by extracting fresh, hashed calf's lungs with nine per cent sodium chloride filtering; precipitating the extract by half saturation with $(NH_4)_2SO_4$, washing and dialyzing the precipitate and sterilizing it by Mills's method (6).

into the empty intestine, leaves unanswered as yet the mechanism of this action. Further work will be undertaken to discover how it is possible for a substance in so coarse a state of dispersion to be absorbed so rapidly that the minute amount of it which is absorbed can alter the clotting time of the whole blood. It is possible that the active principle producing this result is not the protein at all, but some smaller decomposition product. But there is as yet no evidence of this; nor are we able to suggest any explanation for the shortening of the clotting time. It will be necessary to examine carefully what factors of the clotting are changed in the blood so altered; whether it is the proserozyme (prothrombin) content, the cephalin content, the reduction of an antithrombin, or some other change. The investigation will be continued in an endeavor to solve these important problems.

SUMMARY

1. The subcutaneous injection of normal saline solution produced no effect within the time limit of the experiment on the clotting time of normal human blood.

2. The subcutaneous injection of a small dose (twenty-two mgs.) of tissue fibrinogen gave an average lowering of twenty-five per cent. in the clotting time of the blood of eleven normal persons, one to two hours after the injection.

3. Iced water, taken by mouth, produced no effect on the clotting time of normal human blood.

4. Forty-five mgs. of tissue fibrinogen, when administered by mouth in ounces of iced water, to each of nineteen healthy adult persons when the stomach and duodenum were empty produced an average lowering in the clotting time of blood of forty-eight per cent.

5. These results confirm the observations of Mills that tissue fibrinogen, when injected subcutaneously, shortens the clotting time of blood, and that the same action is produced more rapidly by intestinal absorption, when administered in ice water when the stomach and intestine are at rest and not digesting.

6. The explanation of this action cannot be given without further experimental investigation, which is at present under way.

The Back or Dorsal Structures From the Internist's Point of View

J. MADISON TAYLOR, M.D.
Philadelphia, Pa.

Let me restate former postulates preliminary to offering some mature observations:

A clinical scrutiny of the back areas, the dorsal structures or the rear parts of the chest and trunk, will often reveal facts of as much, indeed of far more, significance to the internist than to the orthopedist. A host of disorders, or miseries, or disablements, can be there observed—similar in origins and natural history—but capable of more than one line of interpretation and resources for relief.

For the internist to omit such exploration leaves his clinical obligations only half discharged. Unless the back and associated structures come in for appraisal and the application of locally directed remediation to the causal factors at work, the direct or contributory effects often elude the consideration due them. Also: when such graphic symptoms as are shown by the back structures subside, or yield to locally applied remediation, there can thereby be secured a gratifying reduction in peripheral irritations situated in the same line of innervation. Most of these effects are readaptations in the disordered reflex circuits connected with certain outlying, but definitely correlated, sources of irritation. The effects of these are usually displayed as local spastic states, tonic protective spasm. Often these peripheral lesions seem in no way a part of the dorsal disturbance, yet it can readily be shown that they are.

Also such graphic symptoms displayed in the dorsal structures as do arise tend to subside or yield to locally applied remediation. Then can be secured, also, a marked reduction in the peripheral irritations causing them. This comes about chiefly through readaptation or reconditioning of the disordered reflex circuits connected with the outlying, but definitely correlated, sources of irritation.

The modus operandi is, in short, a harmonizing or rebalancing of the reflex circuits involved. In the process of investigation other structures and correlated functional interplays tend to fall into their place. They may not be exactly explainable but demonstrate the infinite complexities with which man, as a vitalized and chemical engine, is endowed. The objective is to restore automatic mobile equilibrum.

Nature, always of boundless resourcefulness, often needs only relief from hindrances, and to secure favorable positions and encouragements to proceed with her work.

Furthermore, the best influences and instrumentalities are always the simpler, more direct stimuli, and also to begin as near as possible to centres and to apply the right kind of peripheral rousing.

It therefore would seem evident that deep significances reside in impairments of pliancy, mobility, symmetrical balance and of tone in back muscles and static structures, most of which are phenomena of tonic protective spasm due to foci of infections or other irritation. Whatsoever may have been the primary cause of disease, or of mere disorder or disablement, whether we blame germs or pathological chemistry as origins, it is plain that a host of distressful reflex effects do follow, especially those which fail to yield when the primary ailments or disturbances are overcome. These secondary causes, shown in their obstructive, or distressing, or disabling effects, demand relief for themselves. It is a fact that where the primary traumatic, infective or biochemical causes persist, they can be made to yield satisfactorily on the remedying of those associated, or consecutive, or intimately correlated causes. Many disordered states, moreover, must follow upon anatomical or developmental anomalies, occurring in the phenomena of evolution.

So soon as proportionate attention is given to structures of the back, then will cease many omissions, not to say blunders, discredits, or even disasters. The clinical tendency[1] is to ignore this diagnostic field, which is regarded as a sort of fad in those who emphasize it. There is here a domain of effort which must be included in any scheme of exploration for which completeness is asserted.

Expert examination of the back will reveal a variety of facts equally significant with those obtained by experts in exploring such localities as the chest, abdomen, pelvis, the heart and bloodvessels, and the like. Clinical[2] attention has thus far neglected this region; as yet there is little coordinated information on record about the subject.

Backache or tenderness on deep palpation is a quadruple phenomenon compounded of:

1. A tonic spasm exhibited in the paravertebral muscles and their fibrous attachments (clinically a fibromyositis); 2, an irritated, or exhausted, subcentre at the cord level (metamere) corresponding to the innervation of the reflexopathy; 3, a peripheral lesion, or source of irritation, and hence of reflex disturbance; 4, a disturbance of metabolic balance.

Beyond these major and constantly recurring causal fastors lie diverse and sundry associated ones varying in kind and degree as the stage is acute, subacute or chronic, in accord with age, strength, habits, in particular as to the nature of the primary disorder or disease; especially as to the state of energy content.

Pains or tendernesses in the back—as revealed by tactile exploration—are not only among the more prevalent of symptoms, but their significances are too commonly misinterpreted. On examination of the backs of a considerable proportion of those making no complaints of sensory disturbances in that region, there will often be found unsuspected or latent tenderness, soreness and pain.

A study of backs thus furnishes indications of practical significance. Attention need not be confined to those only in which some obtrusive pain, tenderness, disability, deformity or other indicia appear.

Backache, *per se,* deserves relief. It varies all the way from acutest agony through various degrees of misery and impaired usefulness to an embittered existence.

Pain is rarely, if ever, felt in more than one locality at a time. That pain which is most severe dominates lesser pains. When this is relieved other pains are then consciously perceived. The secondary pains sink below the threshold of consciousness while the most severe one occupies the foreground of attention. The series of pains thus may include three or four or more.

Correlated with frank pains are also various kinds and degrees of aches, miseries or depressions, with a more or less sensory basis. The elements of these distresses are often complex blends of weariness, fatigue, exhaustion, or long continued sensory impacts on the consciousness incessantly repeated and unduly protracted. Likewise there is the emotional element of exaggerated attention to the distress; misinterpretation of factors involved causing anxieties lest this or that part, or organ, may be seriously affected.

Backaches are especially common—as has been said—in late age. The causes so uniformly elude location and satisfactory explanation that one of two courses of action is usually adopted; either to accept philosophically the burden of miseries, limitations of activity, or to deny all pain. It is true a pain may be resolutely subordinated, but since its economic purpose is to warn of disease or injury it deserves expert attention and radical remediation, otherwise catastrophe may follow. Such a fool's paradise is worse than an extrahazardous occupation.

WHAT CAN THE INTERNIST LEARN FROM APPRAISEMENT OF THE POSTERIOR SURFACES OF THE TORSO?

Briefly, examination of the back by inspection and especially by palpation, tactile apperception, also by a survey of conformation, proportionateness, relative resistances, sensitiveness, anomalies of adaptation, etc., aids one in the appraisement of many associated phenomena and reflexopathic effects. These reflexopathies bear significantly on the whole domain of sympathetic disturbances in the organism as a whole.

While such evidences as these may seem of more importance to me and others similarly interested, than to the majority of clinicians, certain it is that observation of the back areas is helpful in throwing light upon a wide variety of anomalous, distressful or diseased states due to disturbances of the spinal nerve centres and occurring at corresponding cord levels or metameres.

Evidence on this subject is growing and has already reached respectable proportions through the efforts and interpretations of many. In a former paper presented a suggestive sketch of the subject. A few points will be cited here:

Many, indeed most, maladies, not only the acute but more the subacute and chronic, are reflected in,

[1] During my fifteen years' experience as professor of diseases of children at the Polyclinic Hospital School for Graduates in Medicine, it was my habit to examine the backs of all patients. The older students constantly complained that this was a waste of time and effort.

[2] F. M. Pottenger has recently devised an ingenious and efficient means of appraising tuberculous lesions through spastic phenomena in the back and thorax and shoulder girdle muscles. What is here offered is from personal experiences and inferences. I am confident in one particular: that when the structures of the back come to get the same thorough and critical attention as is given to the organs of respiration, circulation, digestion, and reproduction, we shall come to understand bodily ailments from both direct and indirect (reflexogenic) directions.

and can be interpreted from, the back. It is also a fact—readily corroborated—that a large proportion of distresses, disorders, can be relieved or reduced by induced movements, pressure, heat and other biokinetic procedures directed to the back.

No symptoms may be noticeable except on deep and persistent palpation, or on wide hand pressures, followed by voluntary movements, bendings, rotations and stretchings of the limbs, forceful extension of extremities, preferably while lying prone on the abdomen. Any overtension in the muscles must be relaxed as has been elsewhere described by impacts followed by voluntary movements of the affected muscles.

Of course full x ray studies should be pursued unless the problems are obviously simple ones and symptoms do disappear under the treatment to be suggested.

Among the points to be observed are these:

Pains, tendernesses on touch, sorenesses on voluntary movement, alterations of conformation—only to be learned by many comparative observations on the normal back asymmetries—also twists, lamenesses, limitations of excursus, restrictions, adhesions, but especially whatever can be incriminated as due to spasticities in muscle fibres, chiefly in the erector spinæ muscles, and those of closely associated innervation.

These disorders of shape and density (morphopathies) are caused by reflex overstimulations and due to irritations arising either in the muscles (clinically a fibromyositis) or also—perhaps always—due to irritation as in a viscus reflected to the paravertebral, and hence outwardly to other muscles. Certain it is these often disappear by merely releasing the tonic spasm *in situ*. When they do disappear the irritation in the spinal centres tends to subside, also that in the viscus controlled from the same segmental distribution. Flatulence is a deeply significant phenomenon and is closely correlated to marked fluctuations in blood pressure. As intestinal gas is relieved so do variegated distresses disappear and recoveries progress.

These spastic states in vessels or viscera readily yield to gentle manipulations on such areas of the back as are associated (segmentally) with the area of disturbance.

Relief to the tonic spasm works both ways, forward and backward, and eventuates in relief of many correlated visceral distresses or disorders. The mechanism of reaction is probably due to releasing pentup or retarded energies through biokinetic influencing by, 1, impacts or tapping upon the nerve in continuity; 2, excitation of accessible centres by induced movements (reflexogenesis), and 3, by balancing effects exerted on vasomotor and visceromotor function, hence by improvement in nutrition of the cell bodies in the interdiscal spaces. S. Weir Mitchell called my attention to these points forty years ago and constantly saw patients[3] treated by him in his earlier years in whom the results were amply confirmed.

Among the disabling effects thus removed through orthokinesis are: restoration of not only visceral nutrition, metabolic improvements, and repair, but also in organs of special sense, eyes, ears, of respiration etc., likewise in the whole domain of visceral disturbances.

The special subject here offered is the possibilities of manipulative or manual orthopedics (or better orthokinetics) of the spinal column. What is the common denominator, the mutual integer, or expotential?

It would seem it will be found in a state of relative (spastic) rigidity, loss of normal mobility, of impaired pliancy of the paravertebral structures (those lying two or three inches alongside the backbone) whereby some kinds and degrees of regulative influences are exerted upon the outgoing nerves.

A well established clinical relationship exists between these subsidiary centres in the cord and diseased conditions. These morbidities are shown by alterations in the paravertebral structures both morphogenic or structural, also by pathognomonic sensory disorders as will be later pointed out in diagnostic contrasts. The fact is demonstrable that when these recognizable and uniform phenomena are made to disappear, there follow—coincidentally—a lessening, or modification, or disappearance, of the morbid or distress phenomena.

What causes these manifestations of disorder to disappear so uniformly? It would seem the common denominator or genetic agency is the application of judicious minor shocks or rousing impacts upon the vertebral bodies or those structures intimately associated with them. These seem to afford liberating stimuli to retarded energies. "Biotic energy in order to be effective must be abrupt."—Sherrington.

Good and fairly uniform results follow almost any form of rightly directed gentle, firmly applied force, or emphatic mechanical arousing through spinal impacts or pressures, so long as they are capable of stirring up the reflex mechanisms in definite particulars. Results follow in accord with design, and with known innervations. During states of health these interactions, these comings to rest after stimulation (equilibration), are so automatic that they escape notice. During ill health (maladjustment of function) they are readily noticeable, determinable and controllable. They follow in due order, and in accord with biological laws. They can do no harm unless outrageously violent.

To what can we ascribe the nature of the effects by impacts upon, or agitation or commotion of, the spinal masses?

Several varieties of the same grouping of effects are manifested, all the way from the bone and adjacent structures along the nerves to the part out of gear and—collaterally—by the complex innervation of the vegetative or autonomic nerve distributions.

Some part of these effects are produced by influencing the spinal reflexes of contraction in the hollow and the tubular viscera. These are capable of demonstration upon the heart, the aorta, the lungs, the stomach, the kidneys, and other structures shown by retraction of outline (seen through the fluoroscope).

Some part of the effects are produced by arousing reflex responses in those governing the contraction of bloodvessels (vasoconstriction) whereby the ebb and flow of fluids is activated or enhanced through contraction induced in the arteries; also in the in-

[3]One of these was a man from Arkansas whom I saw in his old age, named William Penn, who had paraplegia. This Dr. Mitchell explained was his first case to yield astonishingly to manipulation of the back, followed by voluntary graded movements.

creased dilatation which follows after release. Not so much can be done to influence arterial relaxation, but after contraction is induced relaxation follows, hence alternations of opening and closing, enhanced current flow, blood and lymph propulsion, hence nutritive distribution.

GROSS PHENOMENA OF DISORDERED STATES REFLECTED UPON THE PARAVERTEBRAL STRUCTURES

The intervertebral spaces and the paravertebral structures are together capable of cooperating and to influence a general or mass movement of the vertebræ of considerable extent. It is fair to assume that the integrity of the delicate structures, constituting the subsidiary spinal nerve centres in the cord, depends in large measure on not only the normal pliancy or movability of these masses but it is beneficial that they should be regularly induced to move, or made to voluntarily move—that is to perform, through passive or active exercise. If they are extensively disturbed, that is, if disease has produced deleterious effects on the nerve cells between the individual bones of the back (intervertebral discs and contained cell bodies) a certain degree of sensory discomfort follows upon their being unduly moved or impinged upon.

Hence arise those significant sensory phenomena to be later described, so useful in diagnosis and the location of the irritation.

When the diseased state has been long protracted, these paravertebral structures suffer morphopathic (mass) changes, hence arise the familiar local bogginess, and later the rigidities, the overtense (spastic) muscles and stiff periarthritic fibres to be described.

The remedial measures consist of gentle, particularized pressures and relaxations, alternating; or by firm distributed pressure—this way and that. Steady pressures on paravertebral muscles induce the reaction of dilatation in the blood channels; whereas alternated impacts or pressures induce contraction. Uniformly a sensory reaction is also induced at the corresponding neuromere.

Another measure, elsewhere described and extolled, is lifting and pulling the skin and underlying structures, a "subdermal traction." As has been shown this measure is peculiarly valuable not only to expedite circulation and to generate or induce local heat, to soothe, to relieve, but also there will be found over an affected spinal area almost always adhesions, and when these adhesions are pulled upon pain is felt there (sensory reflex) and at no other place. Also when they "fetch away" there is a noticeable sound or "snap," a painful tearing of binding fibres. This also is a sensory phenomenon characteristic of a local or restricted spinal as well as a paravertebral irritation. Also skin (subdermal) tractions described afford exceptionally effective spinal stimulation.

TYPES OF MECHANICAL STIMULATION SUITABLE FOR REMEDIES

In all acute, less marked in subacute, and to a lesser degree in the majority of protracted or chronic disorders, there will be found characteristic phenomena upon palpation on the paravertebral structures adjacent to those intervertebral spaces in which lie the cell bodies from which arise the spinal nerves innervating the part affected. Any one can test this for himself. The one proviso which must be insisted on is some accuracy and precision in eliciting awareness.

EXPLORATION OF THE BACK

The patient should lie prone and fully relaxed so that the examiner may have free access to the whole naked posterior surfaces for palpation. This should be done with much deliberation, many pauses, conversing the while with a view of distracting attention from the procedures, casually resting the hand palm downward here and there, noting the character of the structures, and variants in shape, conformation, deformation or tension in larger or smaller masses of structure; also any evidences of resistance in masses which normally should be yielding. These rigidities are due to either psychic hypertension, to apprehension, to strained attention, or to spasm, a tonic protective spasticity whereby one group of muscles takes on extra burdens or "loads" to relieve another which deserves, or needs, relief from excess tension (overload); which in turn is due to some former, perhaps long continued spasm. Thus arise deformations, primarily spastic as a scoliosis, or forward bending, interrupting or irregularities in tension of the large posterior muscle masses, or of the anterior group, psoas, quadratus lumborum, or again there may be hypertension in the gluteal groups, shoulder girdle or external abdominal or diaphragm, and the like.

Or the spasm may have merged into disabilities involving such causes as produce fibromyositis, lumbago, pleurodynia, sacroiliac subluxation (a common cause), coccygodynia, or an original neuritis, as of the sciatic, pubic, crural, and the like. Thus the centres—especially subcentres—suffer overstress and lowered nutrition.

As to sources of possible irritation inducing these spasms they are legion, including the one group which—if the patient be a female—is usually incriminated, viz.: the genito or uteroovarian. If a male, the corresponding group may be suspected, the bladder, the prostate, the urethra or the testicle. In both sexes the gastrointestinal field is rich in contributions to cramp, or protective spasm.

Indeed in that group of distresses which accompany, or distinguish, gastrointestinal catarrh, i. e., constipation, flatulence, colic; also in cardiovascular irregularities, vasomotor imbalances, sweating, dyspnea, spastic constipation, sleeplessness and the like, much radical relief can be afforded by releasing the spasm in the back, which in turn releases the flatulence, the spasm of the pylorus, of the colon, the gallbladder, duodenum, the diaphragm, etc. Thus the source of many "visceral pantomimes" are eliminated.

The method of palpation is important. As has been said, it should begin by appraising the energy status, or general tonus and conformation as recommended, and should proceed by particularized tactile explorations, by pressing gently here and there, and insinuating the finger tips in and about the structures with a view of eliciting anomalous resistances and also latent tendernesses; gently pushing the structures down, across and sidewise, or grasping the dermal structures and gently lifting them, then going farther and seizing the underlying (subdermal)

structures, the surface muscles and fibrous attachments; in short "feeling," or groping among, the surface and subsurfaces of an area. We have here a domain of tactile diagnosis little employed, yet just as scientific as that now highly specialized and established art of palpation, percussion and auscultation employed in diagnosis of thoracic and cardiovascular organs. Indeed, F. M. Pottenger (*op. cit.*) has described a series of reflex diagnostic phenomena appearing in correlated muscle groups serving as a guide to tuberculous and other sources of reflex disorders.

I have been impressed (as have others) with the rarity of tactual capabilities among physicians. While they can be cultivated those who are fundamentally deficient in the touch sense outnumber the others and often "to save their face" belittle its importance or frankly deny the findings.

FACTS PERCEIVABLE THROUGH INTELLIGENT OR EDUCATED FINGER TOUCHES

1. A state of tension, or subtension, amounting to rigidity in the structures parallel to the vertebral axis (chiefly) and also often in the transverse muscle fibres; also a local density, cramp, or tonic spasm or spastic state giving a tactile sensation (to the fingers) of a tightly drawn fiddle string, a clearly defined fibrous resistance.

2. A state of tenderness on pressure is also felt by the patient; often a dull, sometimes a sharp, pain described usually as like a hot object pressed in, or a penetration as by a pointed object, e. g., a finger nail. This is seldom suspected yet none the less pronounced and elicited entirely free from suggestion, it is directly over, or in, the cramped area.

3. By gently alternating the pressures applied above or near this area of rigidity, of tension and subjective tenderness, these phenomena will usually lessen notably even during the procedure or soon thereafter. When applied on alternate days this tenderness gradually disappears and with its passing improvement ensues in the state of irritation in the corresponding area of innervation, also in the structures causing this irritation. The centres are thus tranquillized and apparently become better supplied with blood.

4. During the application of the pressures—after an interval of a few, two or three, minutes and again exerting them the phenomena of tension will lessen yet more. The recommendation is to repeat this procedure three, or better four, times with intervals. The last time of manipulation the phenomena are perceived, both by the physician and the patient, to have usually lessened at least fifty per cent.; often more.

5. Distinct relief will also be found by the patient from distressful phenomena in those peripheral parts affected, e. g., irritation in the respiratory or digestive tract, cough, soreness in throat, etc., or discomforts, notably distresses, tenderness, and the like in the intestines, also those in muscles, joints, or whatsoever area or structure is disordered or diseased.

A Comparison of the Renal Function Before and After Prostatectomy

*With an Investigation of the Concomitant Infection of the Gland and the Genitourinary Tract in Twenty Cases of Suprapubic Prostatectomy for Senile Hypertrophy of the Gland**

NATHAN BLAUSTEIN, M.D.
New York

My selection of this topic is based on a desire to show that the man who is compelled to lead a catheter life is not an absolute derelict from a surgical point of view but is surely destined to a hopeless and miserable end from a medical point of view. A man who has used a catheter for years may come to realize that this instrument is, after all, a curse, even though it may have given considerable relief.

My remarks will be confined to the class of enlarged prostates that are manifested by a train of well known symptoms in the declining years of life and which frequently cause obstruction to the urinary flow. For this reason I prefer to deal with the term senile hypertrophy instead of the general term hypertrophy of the prostate.

Many will bear me out that the victim of senile hypertrophy if not relieved dies of uremia as the final and contributory cause of that malady. It is common knowledge that nothing is so damaging to the secreting power of the kidneys as interference with the channels leading to and from the bladder. The senile prostatic patient can never voluntarily completely empty his bladder. He attempts to void every ten minutes hoping thereby to rid himself of frequency but to no avail. He can only expel, after considerable straining, the amount above the residual, which quantity is ever present in the postprostatic pouch and which causes continual reflexes without giving gratification when voided. The residual urine gradually increases as compensatory hypertrophy progresses and the muscular power of the bladder diminishes, owing to persistent overstrain from the attempt to conquer the obstruction to the urinary flow. Dilatation ensues and eventually the bladder may contain several pints of urine. The walls may become extremely thin or muscular trabeculæ may develop, between which the mucous membrane bulges out in the form of saccules. The results are similar to those due to any other obstruction to the outflow of urine. The ureters become more or less dilated. Whether this dilatation is caused by the increased thickness of the bladder wall, by the pressure of the distended bladder on the oblique insertion of the intramural portions

*From the service of Dr. Leo Buerger at the Beth David Hospital, read before the Clinical Meeting at the Hospital for Joint Diseases, January 16, 1923.

of the ureter, or by simple difficulty of micturition, is unsettled. Whatever the cause, the renal pelvis soon becomes slightly, moderately, or markedly dilated. The kidneys themselves are unable, without deterioration, to withstand the increased pressure, and at an early stage show signs of interstitial nephritis. Moreover, one should bear in mind that at the time of life at which enlargement of the prostate occurs, it often happens that the kidneys are the seat of some other chronic pathological condition besides prostatic trouble.

An ascending infection thus still further damages the secretory power of the kidneys until well nigh beyond hope of repair. It is surprising how much insult such a kidney can withstand for months or years before the entire renal cortex is transferred into a huge sac having no function whatever, beyond the destructive influence upon the body. Such a kidney has lost not only all function of secretion but acts as an ideal incubator for the development of bacterial toxins (Fig. 1). Often phosphatic calculi in pelvis, ureter or bladder are complicating byproducts resulting from decomposed and stagnant urine in the tracts or localities where a superimposed infection destroys the slightest chance of alleviating the sufferer from the complications, much less from the original disease.

Surgical intervention with a view to relieving the kidney and improving its function is the only rational procedure in these cases. Proper preparation of the patient generally and of the bladder particularly are essential to success. However, in many cases where at first glance immediate surgery seems indicated this can be postponed indefinitely, provided the patient is promptly relieved by suitable substitutes. Urine retention from almost any cause can be relieved temporarily by other means than surgery. Profuse hemorrhage from the prostate or bladder neck are the only indications for immediate surgical interference. Mortality in prostatectomy has become largely a thing of the past since the operation has been performed in two stages. This is the result not so much of the disinfection of the bladder as of the detoxication of the patient by the improvement of his changed renal function.

Urine.—The initial complaint of frequency, tenesmus, pain and lack of gratification is in reality but nature's attempt to rid the untiring bladder of its residual urine. This attempt manifests itself, in later stages, by intermittent or continuous dribbling. At this stage the residual urine has reached several pints or more in amount and the musculature of the bladder wall has lost its contractile power and serves merely as a reservoir, allowing as much of the urine to flow away as has collected up to the level of the vesical neck and above that of the postprostatic pouch. This involuntary overflow is usually freshly secreted urine. The urine which constantly remains in the postprostatic pouch with no chance of voluntary expulsion serves as an ideal soil for the development of infection by the Bacillus coli and the staphylococcus. Here, also, commonly phosphatic calculi form and aid in producing cystitis.

In twenty cases, a careful bacteriological and cytological examination of the urine and the prostate gland was made, with the fact in mind that an ascending infection in the pelvis of the kidney must necessarily have its starting point lower down in the bladder. In this analysis Dr. A. Jersky collaborated. His untiring efforts rendered the available data and deductions therefrom possible.

Urine and prostatic examination.—From Tables I and II it will be seen that pus was present in nineteen out of twenty specimens examined. Bacillus coli was obtained in seven instances; Bacillus coli and Staphylococcus albus three times; Bacillus coli and Streptococcus once; Streptococcus albus five times; Streptococcus albus and aureus three times; and Proteus vulgaris once. The prostate alone was the seat of infection in three instances and was sterile in five. The urine alone harbored bacteria in seven instances and was sterile once. The prostate and urine were, simultaneously, the seat of infection in ten cases, but in none were they sterile in the same case. The predominating organisms, their frequency and association were, in order: Bacillus coli; Staphylococcus albus; Bacillus coli and Staphylococcus albus; Staphylococcus albus and aureus; Bacillus coli and streptococcus once and Proteus vulgaris once.

FIG. 1.—Extreme backward pressure produced by prostatic hypertrophy. Note extreme dilatation of both ureters and renal pelves and atrophy of renal secreting tissue.

It is surprisingly interesting to note that two organisms of such varied pathogenicity as Bacillus coli and staphylococcus albus should be the offending organisms in almost an equal number of cases.

Although under ordinary conditions Bacillus coli in the urine may be regarded as an organism of low pathogenicity it sometimes attains a high degree of virulence and may rapidly lead to the death of the patient as, for example, in peritonitis. In rare instances it is even associated with the presence of pus. Fortunately Bacillus coli rarely hinders the progress of a case of prostatectomy. Many attempts to isolate gonococcus were unsuccessful. This is against the hypothesis of some observers that an antecedent gonococcus infection is a factor in the development of prostatic trouble in later years. We likewise failed to isolate the new organism found and described by Dudgeon in 1906. Neither did we isolate Micrococcus neoformans described by Doyen in 1901 as occurring in prostatic and other tumors. In a series of forty-four new growths examined by Paine this organism was found eleven times, but there were no hypertrophied prostates in his series.

Renal function.—In recent years the many improvements in medical and surgical diagnosis of a disease, especially in its initial stage, are chiefly due to the great advance made by physiologists and clinicians in the knowledge of the normal and pathological function of the affected organ. The foregoing statement applies particularly to the kidney.

Renal sufficiency and insufficiency.—The diagnosis of renal disease was formerly made from an exami-

nation of the urine and of the anatomical and pathological condition of the kidney itself. The present method of considering also the sufficiency of the work performed by the separate sections of the kidney, has led to such important prognostic and therapeutic inferences that it will at once be recognized as a great step forward.

Since the introduction of catheterization of the

TABLE I

KIND OF ORGANISM	NUMBER OF TIMES PRESENT	PROSTATIC TUMOR URINE & EXUDATE	URIF	PROSTATIC TUMOR URINE & EXUDATE
BAC. COLI	7	0	2	5
BAC. COLI AND STAPHYLOCOCCUS ALBUS	3	0	1	2
STAPHYLOCOCCUS ALBUS	5	1	2	2
STAPHYLOCOCCUS ALBUS AND AUREUS	3	1	1	1

ureters, the exact division of the secretion of the two kidneys has become a matter of only ordinary technical skill in the handling of the instrument. A pathologic change in the urine is the first sign of impaired function of the kidney. Uremia is the expression of the absolute inactivity of the kidney as a result of destructive disease of that organ or of complete obstruction of the urinary passages. Naturally derangement of the active renal parenchyma

TABLE II

causes each separate department of the specific work of the kidneys to suffer.

The chemical analysis of the urine.—This affords an insight into the renal functions of salt secretion and selection. A twenty-four hour specimen of urine from kidneys should contain salts in the following proportions:

	Gm.
Urea	21-34
Uric acid	0.2-1.24
Creatinin	0.8-1.2
Hippuric acid	0.3-1.1
Chlorides	10-15
Earthy phosphates	0.6-1.2
Total phosphoric acid	1.5-2.7
Sulphates	1.5-2.7

These figures have, of course, their shortcomings and in the opinions of Von Noorden and Ritter Roseman, Guyon, Albarran, Israel, Rovsing and Tuffier this method of examination falls short of our aim. They maintain that even in the healthy subject, a considerable retention of nitrogen may occur which is balanced afterward by a considerably increased excretion.

Microscopic evidence in urinary sediment.—This method of examination, in itself, is hardly fitted for judging renal activity. Often, however, it opens the way to the anatomical diagnosis of a renal lesion. A large number of observations have proved that even the discovery of renal elements in the urinary sediment need not be regarded necessarily as a pathognomonic symptom of an anatomical lesion in the kidney. Both after the palpation of healthy kidneys and in the socalled harmless albuminurias, casts and renal epithelial cells have been found in the urine when it has been impossible to assume a severe disease of the renal parenchyma. Fischer attempted to prove that by the piling up of acids in the kidney all varieties of casts can be produced experimentally.

Many methods of examination have been employed for the detection of renal disease, and the aim of all is at a functional diagnosis. I shall merely name most of them and dwell only on the two which have a direct bearing on this paper and which are indispensable, the most popular and the most extensively employed methods of today.

The various methods (old and modern) are:—1. Determination of the toxicity of the urine. 2. The estimation of the content of urinary pigments. 3. Cryoscopy, the estimation of renal function by determination of the molecular concentration of the blood —freezing point. 4. The estimation of the index of refraction of the urine. 5. Measurement of the electrical conductivity of the urine. 6. Coagulation time of the blood. 7. Method of experimental polyuria. 8. Methylene blue test. 9. Rosaniline test. 10. Potassium iodide test. 11. Sodium salicylate test. 12. Fuchsin, diastase, lactose, etc. 13. Indigocarmin test. 14. Phloridizin method. 15. Estimation of renal function by means of nephritic test meal (Hedinger and Schlager, Mosenthal). 16. Phenol sulphonephthalein test. 17. Blood chemistry analysis.

Phenolsulphonephthalein.—Abele and Rowntree have determined that this drug is rapidly excreted practically by the kidneys alone. The function of the kidney has a special significance in cases of enlarged prostate with retention. This retention can cause cystitis, dilatation of the ureters, varying grades of hydronephrosis or atrophy of the renal parenchyma. Infection invariably leads to pyelitis, a diffused or localized pyelonephritis, or pyonephrosis. These inevitable complications are often difficult of recognition and are overlooked. Owing to extremely favorable results, recent therapeutic measures tend more and more toward a radical suprapubic prostatectomy. This is less dangerous than the regular introduction of catheters, copious hemorrhages, onset of uremia and, most serious of all, malignant degeneration of the parenchyma of the gland. The basis for a successful result lies not only in a satisfactory condition of the patient, but in the sound functional condition of the kidneys. The phthalein test, a trustworthy guide in the correct interpretation of surgical

risks, has not only supplied us with most valuable diagnostic and prognostic information, but has furnished the incentive to numerous investigations into the functional activity of the kidneys. Neglect to employ the phthalein test of the renal functions before every prostatectomy is today unthinkable. Rowntree and Geraghty have employed the test in one hundred cases of urinary obstruction, mostly due to prostatic hypertrophy. In the majority, the test indicated some degree of renal impairment. Studying the excretion of this drug in several hundred normal individuals after subcutaneous injection, they obtained the following results: the drug appears in the urine in five to eleven minutes; thirty-eight to sixty per cent. (average fifty per cent.) being excreted in the first hour after its appearance in the urine, and sixty to eighty-five per cent. in two hours, only a trace being present during the third and fourth hours. Referring to the excretion of this dye in the cases of hypertrophied prostates they maintain that if the commencement of excretion is delayed by more than twenty-five minutes and the quantity of the salt excreted in the first hour sinks below twenty per cent., the operation must be postponed and preparatory measures instituted. Repeated tests are the only guide as to the advisability of surgical procedure. There can be no antagonism to their view as to delay of surgical interference. Without extreme caution in the choice of an anesthetic and in the proper drainage of the bladder before the operation, a chronic prostatic is a poor surgical risk.

The degree of retention, to a certain extent, parallels the age of process. The prostatic cases in which surgical relief is sought are those showing a high degree of pyelonephritis. This is especially true for those cases where the patients are poor, live in unhygienic dwellings and lack the intelligence necessary for the use of the aseptic catheter.

A glance of Tables I and II will show that nineteen out of twenty patients suffered from a concomitant infection somewhere along the urinary tract. In my series of twenty cases of suprapubic prostatectomy the phenolsulphonephthalein test was employed four times on every patient (see Table III).

Limitations of phenolsulphonephthalein test.—The scope of this test is limited. Of equal, or even greater importance, is the estimation of the nonprotein blood constituents through blood analysis because the phenolsulphonephthalein test does not indicate the condition of the kidneys in retention of objectionable constituents of the body for a long period of time, so that it fails to show accurately metabolic changes as far as nonprotein nitrogen retention is concerned. This fact was illustrated chemically by Foster who reported a case of advanced kidney disease showing a normal phenolsulphonephthalein output yet the patient died. In any major operation, particularly prostatectomy, nephrectomy or nephrotomy, the prognostic information regarding the functional activity of the kidneys, which the estimation of blood urea, creatinin and uric acid will give, is indispensable.

The normal blood content of these three end products of nitrogenous metabolism may be given as: urea nitrogen, twelve to fifteen mg., creatinin, one to two mg.; uric acid, two to three mg.; all calculated per one hundred c.c. blood.

Early cases of interstitial nephritis are accompanied undoubtedly by an appreciable rise in the blood uric acid, although a rise in the blood urea can be taken as a safer sign of impaired kidney function. Creatinin appears to be more readily eliminated than uric acid or urea, and it is not, as a rule, until the blood urea has doubled or more than doubled the normal that there is a very appreciable increase in this purely endogenous waste product derived, apparently, from muscular metabolism. Cases with high figures for urea but without marked creatinin retention, generally show improvement under proper treatment, while a case in which the creatinin retention reaches 3.5 mg. per one hundred c.c. blood should be viewed with grave concern. The amount of creatinin excretion serves as a most delicate index for renal function. Along with the retention of these nitrogenous products there is, naturally, retention of other salts, chloride and phosphates. When phosphate excretion is diminished, bringing about an increase in the (acid) phosphate in the blood and tissues, an acidosis results which lowers the carbon dioxide combining power of the blood. These cases are poor surgical risks, unless the patient is operated on under local anesthesia.

SUMMARY OF RESULTS AND FINDINGS:

1. All the patients had resorted to catheterization more or less regularly at the onset of retention.

2. The patients varied in age from fifty-six to seventy-nine years.

3. The prostate weighed three to thirteen and a half ounces, the average being six ounces.

4. The majority of the patients (fifteen) had been entirely dependent on the catheter for fifteen months to six and a half years, and these were in broken health.

5. The blood pressure varied from 185/120 to 215/140; the average being 189/133.

6. Two patients suffered from asthma and chronic bronchitis and one of these died from hypostatic pneumonia five days after the second stage. In one there developed phlebitis of the right leg eight days after the second stage and recovered from it in three weeks. The probable cause was a septic embolus due to the packing of the prostatic cavity to control an annoying and persistent oozing.

7. Four patients had also vesical calculi and glycosuria.

8. The suprapubic route was the choice in all cases.

9. The first stage in all twenty cases, was done under local anesthesia (novocaine two per cent.).

10. Nitrous oxide gas and oxygen were used for the second stage in all cases.

11. The average interval between the first and second stage was nineteen days, the longest twenty-seven days and the shortest twelve days.

12. The average phenolsulphonephthalein output for first and second hours two days before first stage was thirty-eight per cent. The highest phenolsulphonephthalein output for first and second hours two days before first stage was forty-seven per cent. The lowest phenolsulphonephthalein output for first and second hours two days before first stage was thirty-one per cent. The average decrease in the amount of excretion of phenolsulphonephthalein eight days after the first stage was nineteen per cent.; the greatest twenty per cent.; the lowest eight per cent.

The average improvement in the phenolsulphonephthalein output two months after the second stage was twenty-seven per cent.; the greatest thirty-four per cent.; and the lowest twenty-two per cent. An explanation is necessary concerning the drop in the phenolsulphonephthalein eight days after the first stage. As soon as drainage of the bladder is established after preliminary cystostomy, there is a sharp reaction upon the secretory power of the kidney. This is accounted for by the assumption that as soon as the back pressure is relieved decompression of the parenchyma follows. (Table IV.)

13. The average stay in the hospital was forty-one days, the longest fifty-one, and the shortest twenty-nine.

14. In sixteen cases no drainage of the bladder was resorted to after the second stage.

15. Moderate bleeding after enucleation in four cases was an indication for drainage of the bladder after the second stage, through a medium sized rubber tube. This is essential for packing the prostatic cavity to control hemorrhage, as it keeps the bladder opening separated and so facilitates the introduction of a packing by the finger; also for aiding the easy expulsion of clots which may accumulate in the bladder from slow oozing; and, finally for preventing in some measure the infection of the wound. Heretofore, all cases were subjected to tubular drainage after the second stage for eight to twelve days. The wound was thus prevented from collapsing and from quick healing. The prolonged use of the drainage tube was responsible often for persistent suprapubic sinus. Experience has taught us (Mayo Clinic, Victoria Hospital, Montreal) that other things being equal, the wound fares much better if the bladder is not drained artificially after

the second stage. The adoption of his method resulted in absence of pain in the wound and in the complete comfort of the patient. He was able to sit in a rolling chair four days after the second stage, and his wound healed in ten to sixteen days instead of in three to six weeks.

16. Two months after the second stage the patient could retain urine in his bladder for two to three hours without discomfort. In all cases except three, the patients were free from nocturnal urination two months after the second stage.

CONCLUSIONS.

1. It appears from a bacteriological examination of tumors of the prostate that microorganisms cause inflammation which produces enlargement of the gland, but bacterial infection is a secondary event and similar to that which so often occurs in tumors elsewhere in the body.

2. A bacteriological examination of the urine may throw little light on an examination of the prostate.

3. There is no evidence to support the view that enlargement of the prostate such as is referred to in this paper is of gonorrheal origin.

4. There is complete relief from the symptoms after operation, no matter how many years the patient has been dependent on the catheter.

5. Sexual vigor, contrary to the general belief, is materially enhanced.

6. The operation of prostatectomy is a surgical success. By this is meant that in all cases of adenomatous enlargement of the prostate gland, when the operation is properly performed and the after-treatment closely supervised, an absolute and permanent cure results; the patient regaining his power of retaining the urine at will and passing it naturally.

7. There is no relapse of symptoms even with lapse of time.

8. Kidney function is enhanced materially and the entire organism is benefited to an extent equivalent to a rejuvenation of ten years or more.

A complete bibliography will appear in the author's reprints.

A Review of an Important Problem in the Study of the Growth and Development of Children

JOSEPH H. HIDEN, M.D.
Pungoteague, Virginia

In this age of great progress, when our attention is especially called to preventive medicine, every general practitioner of medicine should be specially interested in the growth and development of children. Here we have a field of study amply sufficient in its scope to demand the most careful work, the profoundest acumen of the most intellectual and talented of our profession.

In dealing with children we should always bear in mind that a mere familiarity with the general, morbid conditions that ordinarily belong to adult life is hardly adequate information for our purpose. That we are dealing with the anatomical structures and organs of these little ones in their formative state, and that the correlative relations of these organs, structures and physiological functions are more delicately responsive than are usually found in life of maturity should be discarded.

This is true, not only with regard to the highly sensitive nervous system with its phenomenal responses of reflex irritations, but with the sympathetic responses of the digestive tract, the glandular system and the delicate organs of internal secretion. Moreover, the correlative relations of the functions of these structures and organs are so delicately constructed that a disturbance in one of these is so often followed with disorders in others. Often several of these functional disturbances appear to be working in a vicious circle. This is especially true in some cases of thyroid insufficiency with its influence on the digestive tract (Barker). In such cases it is often difficult to be sure of the primary cause in this cycle of disturbances. In the light of this it is obvious that a careful study of the entire subject of sympathetic responses, involving the nervous system, organs of internal secretion, and the functions of the digestive tract is essential in fitting us to treat intelligently the numerous disorders arising from these sources in the early years of childhood.

In viewing this complex subject and the varied literature of the most noted specialists, one is often more confused in reaching definite conclusions than if his reading were a little less, and his personal observations a little more frequent and discriminating. Personal observations of reciprocal responses in the correlative relations of anatomical structures and organs of the body give us a degree of confidence in dealing with our patients that scarcely anything else can supply. It is through these personal, practical observations that we have, within the last decade, been able to make definite progress in dealing with some of the most important problems of the growth and development of childhood—yes, amid the numerous, hazy theories and dreamy speculations, mingled with complex, scientific experimentations, the plain, practical observations are at last coming forth—namely, that the growing child requires certain definite, nutritive substances for growth and development. When nature and environment do not supply these, artificial measures must be taken.

There is probably nothing that illustrates this more impressively than the organized efforts that are being taken on the goitre problem. For many years the thyroid gland has engaged the attention of the medical profession. Its relation with the other delicate organs of internal secretion has been a subject for complex discussions. Every phase of disturbance, organic and functional, has been studied

and classified with wonderful skill and accuracy, ranging from the most pronounced exophthalmic goitre to that of myxedema; and all these different phases have been studied in their relations to other diseases, functional disorders and sympathetic correlations of other organs, glands and anatomical structures. And yet, with all these scientific investigations and elaborate discussions, it is almost strange to see how slow we have been to put into common sense practice the most practical and useful observation in regard to the prime function of the thyroid gland; namely, that of iodine nutrition.

It is now an established fact that iodine nutrition is an essential ingredient in our food for the maintenance of health, and that iodine poverty is not only felt by the general system in various ways, but is the dominant factor in the causation of simple goitre, and in some cases, even other forms of goitre, throughout the country. Though evidences of many years standing in the support of this statement, along with a steady, progressive accumulation of additional evidence to this end were being considered and digested, no organized effort to handle the goitre problem in this country was crystallized until 1918, when the selective service regulations brought out the fact that northern Michigan and Wisconsin had a great public health problem to solve, since it was found that in the examinations of certain groups of registrants as high as thirty percent. were incapacitated for army service (Olin). Near this time the reports of Kimball Marine's work in Ohio, at Akron, Cleveland and other localities, attracted additional interest. And later, 1921, Leven's second paper on the prevalence of goitre created still greater interest in the medical profession. In this paper it was shown "that of 1,783 persons examined in Lake Linden, Mich., 1,146 had thyroid enlargement." Other investigations in Michigan later on, by Dr. Thomas Marsden and others at Iron Mountain, revealed the fact that out of the number examined in this survey fifty-four per cent. had perceptible thyroid enlargement (Olin). Again, in 1922, Dr. C. C. Slemons, health officer of Grand Rapids, instituted his survey in that city; and from this it was shown also that out of twenty-six thousand children examined thirty per cent. gave a positive thyroid enlargement (Olin).

While many goitre surveys were being made throughout the various goitre sections of the country, and the interest in the goitre problem was on the upward surge, other measures were taken to establish a relationship of goitre in these sections with the natural food supply in its ratio toward iodine.

In these investigations conducted by McClendon and others, after he had examined one hundred specimens of water from the various sections of the United States, and had studied the various goitre surveys that had been made, stated that he believed the amount of simple goitre in the United States varied inversely with the amount of available iodine in the food supply of the areas (Olin). Many other investigations conducted by other observers, when considered carefully, seem to support this view. Indeed, the preponderance of evidence brought out from these goitre surveys has established beyond question that simple goitre is almost invariably caused by iodine starvation, and this fact has impressed the leading officials of our boards of health.

Other boards of health have taken up the question and are trying to devise the most available way of administering to the public continuous courses of iodine treatment. Among the various measures devised for this purpose the administering of a small percentage of iodine in our table salt seems to be the most popular.

As has been suggested by a number of observers, however, the general public in each state, district or locality will have to be enlightened with widespread propaganda on the necessity for increased iodine nutrition before any general coöperation can be obtained. This course is now being adopted, and we look to the future with interest and hopeful anticipations of a grand success. Indeed, it is to be hoped that this coöperative move will be so widely and generally successful in its great object that the stigma that has long rested upon the medical profession, for the lack of practical application of its knowledge on iodine nutrition to the public welfare, may be removed.

Again, another view of this subject brings out this thought: though it is conceded that simple goitre is generally caused by iodine poverty in the food supply, iodine poverty does not always produce goitre. We may have many patients suffering from iodine poverty, ranging from every degree of hypothyroidism to a most pronounced case of myxedema, and still see no signs of goitre. In many of these cases we have various signs and symptoms of iodine deficiency with the appearance of a sort of selective action for other organs, glands and anatomical structures of the body, while eliminating all appearance of any connection with the thyroid gland. This being true it can hardly be said that even in the most pronounced goitrous regions that the percentage of goitre cases represents the number of persons suffering from iodine poverty; for the percentage of the latter must be much higher. When we apply these facts to the borderline states and districts, and especially to the nongoitrous sections of the country, the proportionate number suffering from iodine poverty, and still showing no signs of goitre, must be more marked.

Now, bearing these statements in mind, it seems to me that this public problem cannot be entirely shifted from our shoulders to our boards of health. Every general practitioner has an individual problem for himself; namely, the study and the detection of iodine poverty among his patients, and especially among the children who fall under his care. This number, as I have already suggested, will be proportionately large; and when we consider also the vast number in this country who are suffering from the results of some phase of latent syphilis and who need iodine nutrition or elimination, the number will be larger still. I do not wish to be understood, however, as advocating the administration of full therapeutic doses of iodine generally and indiscriminately to our patients; but I wish the reader simply to bear in mind the large number of our people, especially children, who are suffering from some degree of iodine poverty in their food supply or in their constitutional needs for a normal meta-

olic activity. And to this end I wish to make some suggestions, not so much upon demonstrable facts as upon the theory of probabilities:

Don't wait for the classical syndrome of myxedema, or of cretinism before considering the possibility of iodine poverty. You will seldom see these advanced conditions in your practice compared to the vast number that are not well marked, and yet, who need iodine therapy. I have found, by personal observations in my practice, that a large percentage of cervical adenitis in children is in need of iodine nutrition, especially in the form of calcium iodide. Of course, many throat specialists and bacteriologists will tell us that the enlargement of these cervical glands come from the lymphatic absorption of infected tonsils, adenoids or nasopharyngeal catarrh and other conditions, and in many cases they are correct. But even in a large percentage of these morbid conditions we often have in the patients a poverty of iodine nutrition, which lowers the patients' vitality and thus favors bacterial infection. Many times have patients applied to me for throat treatment, and were considering my advice to submit to a tonsillectomy when a few days' preliminary treatment with calcium iodide improved their symptoms so rapidly that they soon felt that a tonsillectomy was entirely unnecessary. To prevent such a decision from the patient I find that I sometimes have to withhold the calcium iodide treatment, in cases in which I consider a tonsillectomy advisable, until I have performed this operation. Indeed, it is often surprising to see how rapidly the cervical glands and, many times the tonsils also in children, will shrink and greatly improve under the calcium iodide treatment when administered with a nutritious diet, including oatmeal, eggs and milk, especially.

Returning to the suggestion of detecting in our practice such cases as suggest strongly the need of iodine therapy and yet do not give us what may be called a classical syndrome of iodine poverty (such as is found in cretinism and myxedema), I wish to call your attention to cases that present only one or two isolated symptoms that suggest the condition in question. 1. Notice carefully all children who have enlarged cervical glands. A small percentage of these will be tuberculous and will therefore require somewhat different treatment. 2. Note those who are quite fleshy, with a puffy, waxy appearance of the face. Notice also if these children appear dull, sleepy and rather inactive. Note also in such cases the action of the heart, and see if this is relatively slow and irregular. 3. Note such children as are weak, sluggish and are suffering from a most obstinate constipation, with a distended abdomen that is tympanitic. 4. Notice the eyes of a child and see if they are retracted, with a slit lid and show no animation; and notice if the skin seems rather coarse and dry, and if the child's hair has lost its lustre, and if the eyebrows are scant or absent. 5. Notice the condition of the fingers, and see if these are lacking in normal taper; also examine the teeth and see if they are notched, or are giving way, or showing parallel ridges on the incisors or canines, as we sometimes find in cases in which the parathyroids are also involved, with a calcium insufficiency (Barker). 6. Look carefully for any enlargement of the thyroid, and note if the patient is listless or shows any degree of indifference toward his environment.

Any of these symptoms when taken separately are not at all conclusive; but when taken collectively, give strong evidence of iodine poverty. Any two or three of these symptoms, however, ought to be carefully considered, and when in doubt of the real condition, a week or two of iodine treatment may reveal the nature of the case, or at least clear up the doubt so far as iodine poverty is concerned. Of course, this line of study does not exclude any laboratory work to assist us in confirming our diagnosis. I am only suggesting to the busy practitioner a course of practical clinical observations that ought to serve to put us on the right track, and not as a complete course of study in any given case. So let us use these suggestions as merely a starting point in our work of detecting among children iodine poverty in their food supply, and in their constitutional, metabolic activity.

In conclusion, I wish to say that the subject presents a great field for usefulness, and every general practitioner should be alert in his efforts to give his best talents in serving the children of this generation. Who knows how farreaching our efforts may be?

The Syndrome of Coffee*

HALE POWERS, M.D.
Brookline, Mass.

If caffeine were the only toxin contained in coffee, the effects of coffee and tea would be the same, but they are not and coffee does frequently produce symptoms that can not be accounted for by caffeine alone. It contains essential oils, fats, waxes, and glucosides, and from some of these substances, the toxins that produce the symptoms of coffee poisoning will, no doubt, sometime be isolated. Motor unrest, sleeplessness, and tachycardia may be produced by coffee, tea, and Coca Cola alike, but coffee has a syndrome of its own.

From thirty-six cases that I believe to have been coffee intoxication, seen in the Massachusetts General Hospital and in private practice, I have selected for report twenty, in which the symptoms have subsided on the withdrawal of coffee, thereby leaving no reasonable doubt of the diagnosis. I do not report the other cases because in them the diagnosis could

*From the Neurological Department of the Massachusetts General Hospital.

not be verified by further observation, most of them having been seen only once.

In the twenty cases the symptoms occurred as follows: Vertigo in twelve, headache in eleven, nervousness in eleven, visual disturbance in six, insomnia in four, nausea in three, tinnitus in three, cardiac arrhythmia in two, abasia in two, projectile vomiting in one, acrosyncope in one, and anginoid pains in one. Cardiac arrhythmia may have occurred intermittently in some of the cases and thus escaped observation, as it is probably more frequent than my group of cases would indicate.

From my own data I should describe the syndrome of coffee as consisting of vertigo, headache, scotomata, and nervous irritability, with sometimes other symptoms produced by toxic effect on various parts of the nervous system, either central or peripheral. Most vulnerable is the vestibular system, as shown by the twelve cases of vertigo. When nausea has occurred in coffee intoxication, we do not know whether it has been produced indirectly by disturbance of the vestibular system or, more directly by irritation of the vagus; but the popular supposition that it is produced by irritation of the gastric mucosa by the tannin or by the resins of the coffee does not seem to be tenable. Visual disturbances have consisted of an appearance of clouds obscuring the field, of sparks, or of other scotomata, as in migraine. Tremor is probably from the effect of the coffee toxins on the basal ganglia. The headache may be localized as in neuralgia or in sinusitis, or diffuse, as in the variety known as sick headache. Headache and weakness or depression are the symptoms in coffee addicts that sometimes lead to drug addiction. Aspirin and acetanilide are commonly used to relieve the headache, while more coffee, or other stimulants, are taken to overcome the depression.

The following are some of my cases that illustrate certain points:

Case I.—S. M., an intelligent negro woman, aged thirty-four, had complained of headache, cloudy vision, nervousness, weakness, and a feeling of constriction in her throat for about a year. The headache was orbital. She was drinking only a wellknown brand of invalid coffee, not in excess. She had been treated for some time as a psychoneurosis, but without benefit. The invalid coffee was forbidden and six weeks afterward she reported that all of her symptoms had ceased, except the headache, and that was "not half so bad." Invalid coffee contains very little caffeine.

Case II.—F. J., a married man, aged forty, had vertigo every morning. Once in two or three months he had vertigo so severe that he could not stand, and at those times there was projectile vomiting. There was some temporal headache and objects appeared as though encircled by dust. The bowels were moving daily. He had left chronic otitis media and there was constant lowpitched tinnitus. He had been treated for two years in the Massachusetts Charitable Eye and Ear Infirmary and he had been treated in the catarrhal clinic of the Massachusetts General Hospital. The tonsils had been removed and the nasal septum resected, but no treatment had relieved any of his symptoms. He was drinking three cups of strong coffee a day. One month after giving up his coffee he reported having no more symptoms except tinnitus, which had almost ceased. In th case a group of symptoms suggesting an intracran tumor subsided on the withdrawal of coffee.

Case III.—D. W., chauffeur, aged fifty, had rhythmical tremor of the left eyelid, twitching the facial muscles on the left, too rapid to be a t and tremor of the tongue and hands. He had tw cups of coffee a day. This was given up, and tw months afterward he reported that he was cure

Case IV.—R. N., an unmarried woman, ag thirty-eight, a nurse, illustrates the relation of coff to the taking of drugs. She drank four cups black coffee a day and suffered from severe hea ache and scotomata. To relieve the headache o day she took, at 10 a. m., one thirtieth of a grain strychnine, one half grain of codeine, and five grai of aspirin. At 6 p. m. she fell, without losing co sciousness, but finding herself unable to use her rig arm and leg. There was dysarthria and some apha for four weeks and she could not walk for six weel Evidently she suffered an embolism or hemorrha as a result of overstimulation, as she now has a slig hemiplegia. The urine and the blood Wasserma were negative. The episode was a year and a ha before the time of reporting. She has drunk more coffee since that time and has had no mo headache, vertigo, or scotomata. The cause of t hemorrhage or embolism remains unknown.

When I speak of irritability, I do not mean me nervousness, but irritability as manifested by a normal emotional response. My series includes in viduals in all stations of life, and I have exclud all cases that seemed to be complicated by hyster My belief is that the symptoms of coffee poisonin not attributable to caffeine, are produced by some volatile substances that give the aroma to the fin grades of coffee, and that therefore the socalled bet grades are the more poisonous. As these volat substances may be partly eliminated by boiling, I b lieve that a cheap coffee, prepared by boiling, is le toxic than an expensive coffee prepared in the mo approved manner. When I have allowed tea as substitute for coffee, symptoms of the syndrome coffee have not recurred.

In the literature there is much about caffeine a little about coffee.

Bardier, Leclerc and Stillmunkes of Toulouse (studied glycosuria produced by adrenalin. Th found that in animals under nicotine, glycosuria w produced by adrenalin, but that in animals und caffeine, glycosuria was not produced by adrenali They concluded that the sympathetic system w paralyzed by caffein.

Freidberg (2) describes his method of detecti caffein in the urine by its power of contracting fibr of frog muscle, when in concentration as low as o part in 35,000.

K. Okushima (3) reports a study of the excreti of caffein in the urine after tea and coffee drinkin He found that its elimination, whether from tea from coffee, required the same time; for comple elimination, the required time being between ni and ten hours. He used the method of Freidber described above. He found that in persons who brains were unequally sensitive to caffein, elimin tion was nearly equal. From this I think we mu conclude that susceptibility to caffeine is not or

rily dependent on lowered renal function. From e other toxins of coffee I have sometimes observed nptoms a day after they have entered the body.

Kurt Brandenberg (4) writes on the results of ing up coffee. He says that it is not so unfor- nate as it seemed to be that because of the decline the mark, Germany has not been able to import as ich coffee as she formerly did. He enumerates the lowing symptoms in coffee addicts: vertigo, xious feeling, weakness, weak spells, agitation, and heavy feeling in the heart. He says that some cases present the picture of angina pectoris. He does not mention scotomata and tinnitus.

Endocrines in Relation to Rheumatic Fever and Rheumatoid Arthritis

LLEWELLYN JONES LLEWELLYN, M.B. (Lond.)
London

(*Concluded from page 670*)

IOLOGICAL AND THERAPEUTIC SIGNIFICANCE OF THE COLLATERAL PHENOMENA OF RHEUMATOID ARTHRITIS

Much interest and I think profound etiological sig- icance attach to the fact that cases of rheuma- d arthritis, presenting none of the cardinal symp- ns of exophthalmic goitre, nevertheless exhibit ny of its socalled secondary features. Thus, pig- ntary changes, suggestive of adrenal implication cur often on face, neck and limbs, and such may ecede the appearance of joint swellings, in a limb. Scleroderma is relatively common, also edema, ed, transient and of irregular distribution. Sub- ctive feelings of heat, profuse palmar and plantar eatings, dermographism and extreme emaciation e common to both maladies, as also lowered sugar lerance and a tendency to glycosuria.

The fact that cases of rheumatoid arthritis, in the sence of Graves's syndrome, yet display these sec- dary phenomena is very arresting. Is it not a clear dication that the arthropathies are but one feature a widespread constitutional or neuroendocrine dis- der? Have we not here a clue to the implacable ture of the malady? At first in rheumatoid arthri- the joints are swollen, spindle shaped, but ulti- ately they shrink—just as the skin of the ex- mities previously edematous and sweating, event- lly undergoes atrophic changes, becomes smooth, hite, hairless and in long standing cases, indis- guishable from scleroderma. The explanation, believe, is that in rheumatoid arthritis, as in rheu- atic fever, the preexisting and underlying hypo- yroidism is masked during the early stages of the sorder by coexisting Graves's syndrome, or (as oates and Gordon[1] have recently emphasized) by symptoms of hyperthyroidism with signs of sympathetic excitation; while in the later stages of the disorder signs of hypothyroidism again become insistent with its associated sympathetic depression.

Only in light of those cases in which Graves's syndrome and rheumatoid arthritis coexist are we enabled to grasp the significance of the collateral phenomena of the latter disorder, eloquent as they are of occult endocrine disturbance, indicative not only of thyroid but *qua* pigmentation of adrenal involvement also. Their lowered sugar tolerance suggests also pancreatic insufficiency while the frequency with which rheumatoid arthritis like Graves's syndrome arises after pregnancy or at the menopause is suggestive of ovarian disturbance. Obsessed all too often with the joint swellings, we overlook not only the etiological significance of the collateral phenomena but also the therapeutic indications. Small wonder then that eradication of septic foci and vaccine therapy so often prove lamentably disappointing. But if to these be superadded thyroid or other endocrine therapy, how encouraging are the results!

Thyroid therapy is indicated in cases presenting Raynaud phenomena or solid edema of the legs. In examples dating from pregnancy or prolonged lactation or those with preexisting toxemic goitre, as also in coexisting Graves's complex and rheumatoid when solid edema supervenes through thyroid exhaustion.

That lowered sugar tolerance frequently exists in these chronic arthritides is well established and restriction of the carbohydrate intake often does good. But although I have advocated and practised it for years, I question if it represents the best or the most we can do. We diminish the carbohydrate load to meet the deficient capacity, but why not raise the capacity to deal with carbohydrates? I prescribe thyroid and pancreatin, but I often think that here a trial should be given to insulin. For I have seen rheumatoid arthritis develop within two years of an operation for acute pancreatitis. Again, in instance marked by pigmentation asthenia and low tension pulse, a trial of adrenal therapy seems indicated, especially if there be obstinate joint effusions in which

[1] Vincent Coates and Gordon discussing the clinical features of eumatoid arthritis observe: "Clinically there are many signs of hyper- roidism. Excessive sweating, fibrillary twitchings, a tendency to ordered action of the heart and overbrisk tendon reflexes are met h, and there is often that nervous instability and misapprehension ich is associated with disordered endocrine function. The vasomotor tem is markedly upset, with flushing and even demographia; or a dition of the extremities approaching Raynaud's disease may be nd. The skin shows trophic changes, comprising loss of subcu- eous fat and a glazed appearance with loss of hair."
While the bulk of the symptoms are clearly attributable to hyper- roidism, it is obvious also that the trophic changes in the skin with s of hair, are due to the reverse condition—hypothyroidism. In this mmingling of states of hyper- and hypothyroidism in rheumatoid hritis there is nothing unusual.

adrenalin has proved most beneficial. For these are the lines along which I feel sure a more hopeful era of therapy will dawn for the unhappy rheumatoid patient.

OSTEOARTHRITIS AND ENDOCRINE DISORDERS

I have seen osteoarthritis coexisting with Graves's syndrome and others have recorded the same, but it is rare. The sequence—Graves's syndrome, myxedema and then osteoarthritis of knees and ankles has been observed.

On the other hand, the coexistence of osteoarthritis with goitre is not uncommon, and in my work on *Arthritis Deformans* I stressed the extreme frequency with which osteoarthritis of the knees—in women at the menopause is associated with partial or complete myxedema. Lastly, the overlapping of the specific lesions of osteoarthritis and acromegaly is of interest in view of the frequency with which changes in the thyroid and pituitary occur in the latter affection.

SUGGESTED IDENTITY OF ARTHRITIC AND SUBTHYROIDIC DIATHESIS

The intimate interactions, alternations and coexistences of the foregoing arthritic diseases with endocrine disorders has convinced me that the latter form the core—so to speak—of the arthritic diathesis. For myself I believe that the arthritic diathesis is synonymous with the subthyroidic diathesis. Thus, as we have seen, signs of subthyroidism are prominent features of the rheumatic child and as a man can no more escape from his diathesis than from his temperament, the same forms, I feel sure, too, the pathological substrate of the rheumatic fever which the child but too often develops after puberty. True, the symptoms of rheumatic fever may for the time mask the subthyroidism, but subsequently thereto it comes again to the surface and forms—as I believe—the interconnecting link between the rheumatic fever and a subsequent rheumatoid arthritis. Fortunately in the majority of instances rheumatic fever is not followed by rheumatoid arthritis and in them we may assume that endocrine equilibrium is more stable or more probably they lack or are unexposed to those agencies, environmental, infective or others that tend to depress endocrine activity. The menopause is a period of endocrine instability, hence presumably the reason why osteoarthritis so often arises at this period. Moreover, signs of subthyroidism are often present, in gout, and as that great physician Goodhart remarked—the frequency with which gouty subjects give a history of rheumatic fever in early life is highly suggestive.

In furtherance of my contention that a subthyroidic substrate is at the root of rheumatoid arthritis, I would cite two dramatic instances. Thus in a case of Graves's disease under Pauchet a thyroidectomy was performed and consecutively a state of rheumatoid arthritis with scleroderma supervened, which, however, relented to thyroid therapy. Again, Peppo Acchiote cites the case of a woman aged twenty-eight with hypertrichosis of chin and neck. It was treated by exposure of the affected region to x rays and coincidently a condition of rheumatoid arthritis and myxedema ensued and was well established after the eighteenth seance. Proving rebellious to antirheumatic treatment, Acchiote resorted to thyroid therapy which resulted in the dramatic clearing up of the co ditions. These examples afford almost experimen proof that partial thyroid ablation, or thyroid atrop following irradiation through the subthyroidism duced—may determine the onset of rheumato arthritis, and incidentally suggests the reason w scleroderma is relatively common in former malad The same sequence as we have seen may follow th roid exhaustion following preexisting Graves's sy drome or other thyroid exhausting factors. Here a we find an explanation of those hitherto unexpl able but wholly authentic instances in which rheum toid arthritis has ensued suddenly after acute frig viz., the depressing effect of such psychic factors the functional efficiency of the thyroid. I cann close this section more pertinently than with a qu tation from Mutch's masterly study of *Alimenta Infections* in two hundred cases of chronic arthri Thus he observes: "Chronic infection frequen damages the thyroid gland. In the present ser minor forms of subthyroidism were very comm while welldefined myxedema or goitres of consid able size were seen in fourteen per cent. of the cas There is an intimate association between immun reactions and the functions of the thyroid glan The dry extract of the thyroid was given in all su cases with great benefit to the joints."

RHEUMATISM AND GOITRE

Chomel long since said that rheumatism was r either at the Poles or at the Equator, but preval throughout the Temperate Zone, and especially hum or low lying alluvial or marshy districts. That it not entirely a matter of latitude is shown by great difference in incidence of the disease in d tricts of the same country. Such discrepanci moreover, obtain in regard to places, which in matter of climate and exposure are practically iden cal. It seems obvious, therefore, that other fact are concerned and there is some reason to believe t relative differences in soil occur in augmenting decreasing the liability of the inhabitants to rh matic manifestations.

At the same time it must be confessed that possess little or no exact information. But ex rience has shown that where predisposed persons actual sufferers from rheumatism migrate from rheumatic locality they often lose their rheumati just as goitrous subjects lose their goitre when th move to a nongoitrous locality.

As to soil, the belief that rheumatism is associa with limestone formations with their frequent c relate hard water is widespread among the laity a it is worthy of note that such geological formati are, if not exclusively, at any rate favorite hau of goitre. Again, though goitre evinces a predil tion for mountainous regions, we must recollect— Berry points out—that it is rare or unknown in Scottish Highlands and in Norway, and further, he observes: "speaking generally it may be said t goitre is more often found at the foot of a hill mountain than near the summit." In keeping w this, it is now well established that goitre is extrem common in low lying alluvial or marshy distri abutting on canals, rivers or estuaries with their bility to floods, and are not these precisely the regi where rheumatism in all forms abounds?

Seasonal incidence.—Both here and in the United States rheumatic fever, and in children endocarditis and carditis, tend to appear in the spring, and we may well ask—why this periodicity? The same holds good of tetany, too. Again, as McCarrison points out, new cases of goitre arise and preexisting goitres swell during the spring. Spring connotes chemical changes in the blood and endocrine glands—notably the thyroid. Thus the blood content of calcium and inorganic phosphates is at its lowest ebb in May—so, too, the iodine content of the thyroid. Is not this synchronous seasonal incidence of rheumatic fever, tetany and goitre somewhat striking, having regard to the clinical affinities of rheumatism for tetany and tetany for goitre?

Influence of sex.—In endemic goitre McCarrison states that up to the age of puberty goitre affects the two sexes almost equally. It is, if anything, more common in girls, but from the age of puberty onwards females are much more liable.

Turning to the recent valuable Report of the Ministry of Health on the *Incidence of Rheumatic Diseases,* one of the most striking facts elicited is the higher incidence of acute rheumatism (rheumatic fever) in insured females. Thus it states: "Not only are our insured females from sixteen to twenty-four attacked much more frequently (as 5:3) than the insured males of similar age, but that in the next age group twenty-five to thirty-four females are attacked three times as often." Later it states "our experience as to this higher incidence of acute rheumatism upon insured females is supported by the Leipsic statistics." Also if both acute and subacute rheumatism[1] be taken together the predominant incidence among women still obtains. The insurance ages for females being over sixteen, figures are unfortunately not available as to the relative incidence of rheumatism in children. But Poynton's statement that a female child with an hereditary rheumatic tendency tends to develop rheumatism more often than a male in the proportion of three to two seems to indicate that as in older subjects the incidence is higher in females than in males. Lastly, the findings re hereditary or familial liability are, the report states, "certainly consistent" with the "deeply grounded belief that acute rheumatism is a family disease." It may be added, too, that—contrary to general opinion—in muscular rheumatism the female attack rate is considerably higher than the male in every are group.

Passing to rheumatoid arthritis, the report states that its findings fully bear out Strangeway's statement that more than three women suffer from rheumatoid arthritis to every man. This is if anything an underestimate for taking 240 consecutive cases out of my series or rheumatoid patients, there were thirty-nine males to 201 females, a proportion of one to five or 16.25 per cent., and 83.75 per cent. respectively.

The findings of the report fully bear out the well established fact that the incidence of rheumatoid arthritis is higher in the childbearing decades, and contrast it with the relative infrequency of osteoarthritis during that period. They observe that after forty-five the female osteoarthritis rate equals the rheumatoid arthritis rate, while they add "the magnitude of the attack rate for osteoarthritis in older females when compared with the corresponding male attack rate is one of the surprises of the enquiry." This bears out my observation in 1909 that "the frequency with which in women osteoarthritis arises at or near the menopause is remarkable" (*7*), as also my statement that the knees are the common site (fifty-five per cent.). As to a previous history of acute rheumatism, the report found it in sixteen per cent. of the rheumatoid and in fourteen per cent. of the osteoarthritic group. A family history of rheumatism in forty-eight per cent. of the former and of the latter in forty-one per cent. of the females and thirty-two per cent. of the males.

In reviewing the foregoing findings the outstanding feature is the sex difference—the predominant incidence in females of acute rheumatism (rheumatic fever), subacute rheumatism, muscular rheumatism and, during or after the menopause, of osteoarthritis. In respect of goitre, too, we find the same preponderant incidence in females from childhood right up to the menopause with its maximum in the childbearing decades.

Now, the incidence of rheumatism in girls—as opposed to boys—between ten and fifteen, is heavy, and that of goitre also at this period, viz., at or near puberty. The incidence again, of rheumatic fever in the childbearing period is heavy, but much more emphatically that of rheumatoid arthritis, while at and after the menopause the incidence of osteoarthritis increases markedly.

It is clear then that these periods of increased incidence synchronize markedly with puberty, the childbearing decades and the menopause. In other words with those physiological processes—menstruation, pregnancy, lactation—which determine oft recurring or enduring hyperemia of the thyroid—while the heavy incidence of osteoarthritis at or after the menopause again coincides with the senile atrophy which overtakes the thyroid and ovary at this epoch. Needless to say the precise periods, too, at which new goitres arise, preexisting goitres enlarge, or at the menopause undergo involution, or become the seat of neoplasms.

Visualize these peculiarities in light of the subthyroidism of rheumatic children, the thyroid reaction during rheumatic fever, its frequent sequential hypothyroidism and its association with Graves's syndrome. Consider also the subthyroidism of rheumatoid arthritis, its occasional coexistence with Graves's complex, or commonly with hyperthyroidism and subsequent hypothyroidism, and to these add the—in my experience—invariable association of osteoarthritis in women with hypothyroidism, or myxedema, partial or complete.

View these also in light of the therapeutic test—the efficacy of thyroid therapy. That rheumatic fever in the children of actually goitrous subjects, or of the nongoitrous living in endemic regions, though rebellious to salicylates, yet responds if thyroid be superadded. It may be objected that thyroid swelling is not common in rheumatic fever, but how often is swelling or tenderness looked for? Moreover, the absence of noticeable swelling is quite compatible with a chronic process of hyperplasia in the thyroid—and this not rarely, judging from the frequency

[1]Definition of subacute rheumatism in report. Subacute rheumatism—a mild attack of acute rheumatism; pyrexia not exceeding 101°F. responding to salicylate treatment often accompanied by endocarditis without chronic joint deformities.

with which signs of subthyroidism subsequently ensue. On the efficacy of thyroid therapy in suitable cases of rheumatoid arthritis and osteoarthritis, I need not dwell, for they are well established.

Broadly speaking, the treatment of goitre and of rheumatic and rheumatoid affections shows a striking similarity. Iodine, iodine preparations, intestinal antiseptics, vaccines and thyroid therapy, not to mention change of residence, change of locality, water supply and so forth.

The clinical evidence then that these arthritic and endocrine disorders are intricately interwoven is undeniably cogent, reinforced as it is in the sphere of therapy. Inevitably it suggests the further possibility, viz., that the etiological factors responsible for their production likewise overlap or are perhaps identical. Indeed it has often occurred to me that the resemblances between goitre and rheumatism are somewhat striking. Both seem to me hereditary and very definitely familial in distribution. Both, too, I think may be regarded as place diseases, and though one hesitates to class rheumatism as endemic, it seems clear also, that our views as to the endemicity of goitre are undergoing attenuation or enlargement. We say in the same breath that goitre is ubiquitous, and yet we call it endemic. In short, as McCarrison, discussing its distribution in different countries, observes: "while the degree of endemicity varies, it would be difficult to declare any area to be goitre free." In others, as Berry remarks, "it is so widely spread over the whole country, while at the same time it is so slight, that it easily escapes notice, and cases of goitre are often considered to be sporadic which should be more correctly classed as endemic."

The present fashion of exposing the neck has revealed the unsuspected prevalence of goitre in young women and girls in London and other large cities. Does this predicate a low degree of endemicity (*qua* Berry)? Or are they to be regarded—as McCarrison suggests as examples of a simple toxemic goitre "to distinguish them from the goitre of endemic areas with which, however, they are closely analogous in origin?" But more pertinent to my subject is his statement "that toxemic goitre in the mother is of great importance in determining the production of congenital thyroid instability in the child. The symptoms of Graves's disease also may be superimposed on toxemic goitre." Seeing that thyroid instability is so marked a feature of the "rheumatic" child this previously unrealized prevalence of goitre takes on an added gravity and may have something to say to the heavy incidence of rheumatic fever in the methopolis as also, the frequency with which Graves's disease is met with in "rheumatic" subjects.

GEOGRAPHICAL INCIDENCE OF RHEUMATISM AND GOITRE

From this aspect the findings of the Ministry of Health regarding rheumatism are somewhat suggestive. Thus, the death rate from rheumatic fever and cardiac rheumatism is much higher in the north west and south west than in the east and south east counties. The standardized death rate through these disorders is highest in Lancashire and lowest in Norfolk. But Lancashire again, in this respect, falls below certain Welsh Counties, notably Glamorgan. But a very notable feature is the excessive incidenc of rheumatic fever and cardiac rheumatism in fe males in the City of Bristol.[1]

True the Report discloses the fact that the genera liability to endocarditis in females exceeds that o males but this only brings into greater prominenc its excessive incidence in Bristol.

Now, it is admitted that the Cotswolds, the Men dips and the Valleys of the Pennine Range are al noteworthy haunts of goitre. It is worthy of not then, that the greater portion of the City of Brist lies in Gloucestershire, the remainder in Somerset shire. In short Bristol is located in and encircled b two counties—noted seats of endenic goitre. Thus we find it frequently in the villages in the Cotswol valleys of Gloucestershire, anl upon the carbonif erous limestone of the Mendip Hills—the villag of Chiselborough has long been noted as the sea of endemic cretinism, now I believe, extinct. Agair the river Avon upon which Bristol stands rises in th Cotswold—coursing through parts of Wiltshire an goitre is certainly endemic in some of the village along its banks.

This overwhelming incidence of rheumatic feve and cardiac rheumatism in a city lying in a goitrou district, and this among the female population i arresting. Without statistics as to the incidence o goitre in Bristol itself, it would seem impossible t follow the matter further. But seeing the intimat association of rheumatic fever with intercurren thyroid swelling with Graves's syndrome an sequential hypothyroidism, and also the rebelliousnes to salicylates of rheumatic fever in the children o the goitrous or those resident in endemic areas, would affirm my belief that there is some deepseate connection between the exceptionally heavy incidenc of cardiac rheumatism in Bristol and the endemicit of goitre in its environs.

Turning to Glamorganshire, in which the deat rate is higher than even Lancashire, we find here als goitre is endemic along the Barry estuary, an according to Hirsch in many parts of Wales, whic is interesting seeing that the death rate in Merioneth Montgomery and Brecknock also surpasses Lanca shire. Nevertheless, in Lancashire too, Hirsc reports endemic of goitre at Bolton, Accrington, an other places, while Hutt recently commented on th relative frequency with which thyroid swelling found in school girls in Warrington. The incidenc of acute rheumatism also appears to be heavy i Nottingham and it is suggested may be related t "lowlying riparian sites on made ground"— common site for goitre and Hirsch states that goitr is endemic in the coal districts of Notts. Stretchin towards Derbyshire, a noted haunt of goitre. Un fortunately for our purpose there are no repor forthcoming as to the incidence of rheumatic diseas in Derbyshire. The lowest incidence of rheumatis is in Norfolk, Anglesey and Cornwall. As to goitr in the first named Berry states "it has been asserte

[1]Carey F. Coombs writing on the incidence of fatal rheumat heart disease in Bristol (*Lancet*, 1920 ii. p. 226) found the avera annual number of deaths from rheumatic heart disease defined his method was seventy-one (or seventy-three if chorea were include on an average population of 251,974, a death rate of 282 per millio which is immensely high compared even with Lancashire, and sufficient to show that even after allowance has been made for t increased number that his method would show compared with resul obtained from ordinary certification records, there must be a hi death rate from this disease in Bristol.

that part of Norfolk is affected. Some of the villages a few miles to the west of Swaffham, are, however, certainly not affected." As to Anglesey this authority was informed that goitre "is probably absent from the whole island" and as to Cornwall, I can find no record so presumably it is not a marked feature.

As to rheumatoid arthritis, there is some excess in the south western and south eastern parts of England, and of gout a striking excess. Of osteoarthritis the main excess is in males in the North Western Division and in the females in the South Western region.

Need for further inquiry is obvious, but it does appear to me that where rheumatism abounds, endemic goitre also prevails, for generally speaking, rheumatic affections seem more common and more virulent in those regions through which the valleys of the Cotswold, Mendip and Pennine ranges run. Moreover, if my contention be correct that the arthritis diathesis is but another name for the subthyroidic, then it is not surprising that these diseases, especially rheumatic fever and rheumatoid arthritis should be more common in goitrous districts. I would remark too that subthyroidism emphatically favors the effective action of the generally accepted determinants of rheumatic fever, viz., cold and muscular overexertion.

For subthyroidism implies intense sensitiveness to cold, also diminished catabolism and diminished elimination of waste products. As I have said the environmental conditions that make for goitre make for rheumatism and the decrease of goitre and cretinism in the valleys of the Savoy, Pyrenees, etc., in sequence to drainage of wet, marshy soil, and the making of regular water courses and the like renders it imperative that such should be undertaken on a large scale in areas of endemic goitre. The prevalence of toxemic goitre too, clearly indicates that routine examination of school children from this standpoint, with a view to its early treatment and to the end of preventing the hereditary transference of thyroid instability to such offspring as may come to them in later life.

Epilation With Diathermy

A Preliminary Report

ADOLPH ROSTENBERG, M.D.
New York

One of the most trying problems in cosmetic dermatology is the successful management of hypertrichosis. The unfortunate sufferers of this disfiguring ailment fall an easy prey to the advertising quack who promise a cure but usually fail.

So far we only know of two methods in the treatment of hypertrichosis: the x ray and electrolysis. Unfortunately the x ray, while an excellent agent in so many dermatological conditions, fails here and should be thoroughly discouraged, as the dose, required to produce a permanent alopecia, must exceed an erythema dose and is therefore likely to produce skin atrophy and telangiectasias, which are much more disfiguring than the original condition.

The second method is epilation by electrolysis, which, if used properly, is safe but unfortunately not free from many drawbacks. The main objection, aside from the slow progress and considerable pain to the patient, is that in the hands of the average operator only fifty to sixty per cent. and done by a skillful man, perhaps seventy-five per cent. of all the hair treated is successfully removed in one sitting, the balance will reappear, as the needle, no matter how skilfully inserted into the hair follicle, does not always strike the hair papilla in order to destroy it. The time necessary for the treatment of one hair averages about a minute, so that hardly more than twenty to forty hairs can be treated in one sitting. This method is usually most discouraging. Any improvement on this method should thus be welcome.

For the last few months I have treated these cases with the bipolar current of a modern high frequency machine, using electrocoagulation. The needle is connected with one pole and another metal electrode is attached to the skin. The needle is then inserted in the hair follicle and the current turned on with a footswitch, after having set the machine, to give the smallest possible spark. A current of about 80 milliamperes is usually sufficient. It takes about ten to twenty seconds for the successful removal of a hair, which is in almost one hundred per cent. perfect. The papilla is destroyed as the hair comes out without the slightest pull. The reason is that the coagulation spreads over a large enough area to destroy the papilla, even if the point of the needle does not touch it. By this method from seventy-five to one hundred hairs could be removed in one sitting and the percentage of recurrences is negligible. The pain is considerably less than caused by electrolysis. I have not noticed any scarring following the treatment.

CONCLUSION

While I have only used this method for a comparatively short time, I have been favorably impressed by its possibilities.

152 East 179th Street.

Practical Therapeutics

THE THERAPEUTIC RELATIONSHIPS OF DIGITALIS AND STROPHANTHUS*

EDWARD E. CORNWALL, M.D., F.A.C.P.
Brooklyn, New York

Digitalis and strophanthus have been classed as drugs with the same or a similar action. James Mackenzie, as late as 1920, in speaking of their action, said: "I could never in practice detect any difference" (1). In the general estimation strophanthus has been considered a sort of inferior digitalis, unreliable in its preparations and dangerous. Many years ago I concluded from clinical experience that notable differences existed in the actions of these two drugs, and that in some cases of heart failure strophanthus produced more favorable effects than digitalis. Writing in 1905, I said: "In uncompensated valvular disease in which the prognosis is bad as regards recovery of compensation, strophanthus generally acts better than digitalis. And in dilatation from any cause where the prognosis is bad strophanthus is usually more effective than digitalis" (2). And in 1911: "It (strophanthus) is much more useful than digitalis in the myocardial conditions produced by the acute infections, and it is often of great value, if used cautiously, in the chronic degenerations of the myocardium" (3). And in 1917: "The general indications for the use of strophanthus are those of a direct heart stimulant" (4).

The establishment of the proposition that digitalis and strophanthus differ radically in their therapeutic action depends on getting a certain amount of positive knowledge. Lately such knowledge has become available, and Vaquez was able to say in his textbook of diseases of the heart, published in 1924, when speaking of cases of heart failure over which digitalis had lost its efficiency: "We are obliged to admit that there has intervened some new factor which escapes the influence of digitalis. This factor, over which the drug has no control, is loss of myocardial tonicity; for, speaking physiologically, digitalis is not a heart tonic, as it has often been called. Therefore, it is necessary to search for other substances possessing a more energetic action on the tonus of the heart. This action is possessed in a high degree by the strophanthins" (5). This statement of Vaquez suggests an explanation of the differences observed clinically between the actions of digitalis and strophanthus.

Before discussing further the clinical aspects of the subject, let us review briefly the physiological action of these two drugs.

PHYSIOLOGICAL ACTION OF DIGITALIS AND STROPHANTHUS

Much study has been devoted to digitalis since Withering's notable monograph appeared in 1785, but our knowledge of its physiological action is far from complete. These facts seem to be established: Digitalis is slowly absorbed from the alimentary tract and slowly eliminated or destroyed. It acts on the heart in two ways, directly on the myocardium, and indirectly through stimulation of the vagus nerve and the two elements of its action vary absolutely and relatively to each other with the dose and the condition of the patient.

Describing its effects generally, we may say that in therapeutic doses it regulates the heart's action and improves the circulation in cases where such regulation is needed and the heart is in a condition to respond. In conditions where the heart is acting normally it appears not to slow or otherwise modify notably its action or to change the volume of the circulation; probably because the natural compensatory mechanism nullifies the disturbing effects of the drug. Describing its effects more particularly we may say that it acts directly on the myocardium to increase excitability and to diminish conductivity and indirectly through the vagus nerve, which it apparently stimulates at its cerebral centre, to depress all the myocardial functions. Its direct effect in increasing excitability may be nullified to a certain extent by its indirect depressing effect through the vagus in some of its stages, but it has been affirmed that extrasystoles can be produced by stimulation of the vagus, and Wilson says, "The arrhythmias occur when vagus and sympathetic are both active" (6) and strong stimulation of the vagus may cause its exhaustion with resultant sympathetic preponderance; and certainly extrasystoles are commonly produced by large doses of digitalis. If it directly stimulates contractility, which has been denied, such effect is apparently nullified by its depressing effect through the vagus. It seems not to increase tonicity or the "energy to contract" of the heart muscle. Robinson quotes Wenkebach as saying: "There is no evidence that the drug acts on the obscure property, tone of the muscle" (7) Robinson also quotes Mackenzie as saying that he, the latter, "was unable to determine that the drug affected the heart muscle."

The effect of digitalis in diminishing conductivity, which plays the chief part in its therapeutic action, is produced by both its direct action on the myocardium and its indirect action through the vagus. This effect is determined to a certain extent by the condition of the myocardium.

When digitalis is given in doses large enough to produce toxic effects, certain characteristic symptoms appear, which are, particularly, gastrointestinal, cardiac and renal. Headache is also a symptom, and may appear early. The gastrointestinal symptoms, viz., anorexia, nausea, vomiting and sometimes diarrhea, are usually the earliest to appear, although the cardiac or renal may appear before them. The first symptom of toxic effect on the heart is usually the occurrence of extrasystoles, which may appear occasionally or come so close together as to produce coupled rhythm. Heart block appears when the depression of conductivity has reached a sufficient degree in relation to the condition of the conducting tissue. Auricular fibrillation and alternation of the heart have been noted as toxic effects, especially in cases predisposed to those arrhythmias. Slowing of the heart's rate is not necessarily a toxic manifes-

*Read before the American Therapeutic Society, Atlantic City, N. J., May 22, 1925.

ion unless it should reach a point below normal. In regard to the effect of digitalis on the blood essure, Robinson quotes Eggleston as concluding at "there is no evidence that either digitalis or gitoxin has any direct effect on the blood pressure nen given to men, even in large therapeutic doses." have observed the hypodermic administration thirty-six hours of the equivalent of 105 minims a standardized tincture of digitalis to be attended th a fall in systolic blood pressure of twenty millieters of mercury, the diastolic pressure remaining nstant, and an increase in the pulse rate. When ven in doses large enough to produce death, the st stage of its action, as observed by Robinson and Vilson with the aid of the electrocardiograph, shows ntricular fibrillation (8).

The amount necessary to bring about beginning xic symptoms is stated by Levine and Cunningam to be between twenty-seven and sixty four per nt. of the lethal dose (9).

That the physiological action of strophanthus ffers radically from that of digitalis appears in the escription of it given by Vaquez, who says: Strophanthus is above all a heart poison, on which rgan it has a remarkable action. Soon after the dministration of a lethal dose, the heart beats more owly, the ventricles contract more and more, their utput diminishes and death ensues when the heart, gid, contracted and empty of blood, stops on acount of excess of function. The influence is exted first on the ventricles; the auricles resist longer. inally, it has been proved that the arrow poison cts on the myocardium itself and not on the nerve laments. The arrest of the heart does not depend ither on the intervention of the pneumogastric or f the medulla or cord. . . . Strophanthus, nen, is the heart medicine *par excellence,* the effects f which are exerted exclusively on the myocardium vithout intervention of other factors. Perhaps it ffects conductivity also, as Jamieson has noted, by engthening the conduction time. . . . The limination or destruction of strophanthin is more apid than that of digitalis, but it is not known how t occurs. At all events, the substance is not evacuted by the kidneys, nor by the salivary glands, nor by the alimentary tract, and on account of its rapid disappearance it has no cumulative effect" (10). Vaquez also notes that the actions of strophanthin nd ouabain are identical. In addition to its action n increasing tonicity and depressing conductivity, trophanthus probably has some effect in increasing excitability. I have observed pulsus bigeminus to follow its use in large, continued doses.

Vaquez's statement that strophanthus does not produce any part of its effect through stimulation of the vagus seems to be supported by Cushny's observation, that while a rapid heart slowed by digitalis recovers a portion of its former rate after administration of atropine to block the vagus, a heart similarly slowed by strophanthine shows no increase in rate after administration of atropine (11).

If digitalis stimulates the vagus but does not increase tonicity and contractility, while strophanthus does not stimulate the vagus but does increase tonicity and contractility, the differences in action of the two drugs would seem to be radical, and the correspondences to be limited to increasing excitability and diminishing conductivity.

PREPARATIONS AND DOSES OF DIGITALIS AND STROPHANTHUS

The matter of preparations and dose is of prime importance. A good drug used in unreliable preparations or improper doses can fail to demonstrate its therapeutic value and mislead as to its qualities. This has been the case especially with strophanthus, which has been administered in improper doses; although the unreliability of its preparations is probably much less than has been asserted. The therapeutic dose of digitalis is more generally understood than that of strophanthus, and the variation in potency and stability of its preparations has been largely corrected by standardization.

As the therapeutic effect of digitalis is not produced in most cases until the lower limit of its toxic action has been reached, it is with the beginning toxic action that we have to deal. This dose, as stated previously, is modified by the pathological lesions present. In my recent experience the administration of the equivalent of 225 minims of a standardized tincture of digitalis (fifteen tablets of digipuratum of one and a half grain each), given in five days, produced anorexia, nausea, vomiting and pulsus bigeminus in a young woman with chronic cardiac valvular disease of rheumatic origin, without fibrillation but with inadequate compensation for the recumbent position; which was followed by cardiac dilatation, enlargement of the liver and death in about a week.

In another case I observed recently that no signs or symptoms of toxicity after the administration of 270 minims given in three days to a young woman with compensated mitral stenosis who had lobar pneumonia: the heart action continued good throughout the pneumonia and the patient recovered. And again, I recently observed anorexia, nausea, vomiting and a slow pulse develop in a young woman with mitral stenosis and auricular fibrillation, after taking 180 minims in four days. The patient weighed 108 pounds.

The fact that different amounts of the drug produce beginning toxic effects in different myocardial conditions is an argument against giving it in massive doses to produce quick digitalization, and in favor of giving it in moderate doses to produce gradually therapeutic saturation, so that early symptoms of toxicity can be recognized and the drug stopped.

Cowan and Ritchie sum up the situation as regards digitalis doses as follows: "Sir James Mackenzie recommends a daily dose of one dram of the tincture, divided into three or four doses. French writers advocate massive doses, but the repeated administration of the smaller doses seems to us preferable, as the minor adverse symptoms can quickly be checked by withdrawal of the drug. In our experience smaller doses than a dram may be sufficient" (12).

The rule for the administration of digitalis laid down by Withering in 1785 is as follows: "Let the medicine be given until it acts on the kidneys, the stomach, the pulse or the bowels; let it be stopped on the appearance of any one of these effects."

The question of its dose is closely connected with

that of its absorption, when given by mouth, and especially with that of its elimination. It has been shown that with good action of the kidneys, the equivalent of between twelve and thirty minims of a standardized tincture is eliminated in twenty-four hours, the average being about twenty minims. So in cases where it is desired to maintain saturation at a given point, this can be done, after that point has been reached, by administering daily a dose between those limits suited to the case.

DOSE OF STROPHANTHUS

The dose of strophanthus is a more simple matter than that of digitalis. There is here no question of cumulation; nor is there one of absorption, if the drug is given by the hypodermic or intravenous methods, or to any noteworthy extent, in my opinion, if it is given sublingually. And the dose does not have to be always of such a size as to produce the fullest physiological effect. Strophanthus being truly a heart tonic can be given in tonic doses of varying sizes to meet different indications, as well as in doses as large as the limit of therapeutic response. The dose of strophanthus should be the smallest that will do the work, while that of digitalis should be as large as the patient can stand.

STROPHANTHUS PREPARATIONS

Much has been said of the unreliability of preparations of strophanthus, especially the tincture, and the dangers that attend its use. In my earlier studies of strophanthus I used the tincture and had generally good results with it; now I prefer strophanthin, but I did not use either in the doses recommended in most publications on the subject. I have found by experience that doses considerably smaller than those usually recommended give the best results; and I am of the opinion that the failures to get good results with it and the accidents that attended its use were to a considerable extent due to its being given in too large doses.

It has been maintained that strophanthus given by the stomach is not satisfactorily absorbed. Whether or not that is so, in times past I have obtained what seemed to be good results from such administration. Now, having strophanthin, I do not give it by way of the stomach, but only sublingually, hypodermically, intramuscularly and intravenously.

The different strophanthins cause some confusion because they appear in amorphous and crystalline forms which have different doses. I have found it convenient to use one particular preparation the dose of which I have learned by clinical experience. This dose, as I have learned it, ranges ordinarily from grain 1/1000 to grain 1/250, given every four hours. The first mentioned dose is considered moderate and the second large. A full dose is grain 1/500, every four hours. In emergencies a single dose of grain 1/100 may be given intravenously or intramuscularly, after which no more should be given for twenty-four hours. The variety of strophanthin known as ouabain possesses the advantage of being crystalline and uniform; it is given in doses considerably smaller than the dose of amorphous strophanthin.

(To be concluded)

Treatment of Hay Fever.—Leo von Gord (*Schweizerische medizinische Wochenscrift,* M 15, 1924) states that inasmuch as the etiology hay fever is still uncertain there can be no speci remedy and therefore a detailed history of the in vidual case is of great importance. It should borne in mind, however, that the administration calcium may afford considerable relief and form t basis of future therapeutic and prophylactic mea ures. The author has obtained some very good r sults with it. With the administration of sufficie amounts he observed not only a diminution of t increased excitability of the nerves which produ the attacks of sneezing, but also an improvement the general condition of the patient and an increas power of resistance to various influences.

The best mode of administration is by mouth a the most effective calcium salt is the chloride. Wh a rapid and intensive effect is desired intraveno injection may be used. A ten per cent. calciu chloride (chemically pure) solution is given intra enously, or the double salt of calcium chloride ur may be used. Injection into the surrounding tissu should be avoided as such an injection will produ not only severe pain but also necroses.

Relations Between the Thyroid Gland and th Nervous System.—A. Oswald (*Revue Françai d'Endocrinologie,* August, 1924, vol. 2, page 23 enumerates and comments on the various points contact between these structures in respect of goit and hyperthyroidism, general nervousness, metabol divergences, psychic manifestations, insomnia, tach cardia, states of gastric disturbance and those hyperactive intestinal peristalsis. He emphasizes th evidence that administration of thyroid extract pr duces similar effects in individuals and anima whose nervous system is impaired, but not in su as are in complete health. Thyroglobulin, that iodized globulin, seems to possess the property sensitizing the nerves of the circulatory apparatu It likewise possesses all the other properties di tinctive of the gland and consequently must be i ferred to constitute the thyroid hormone. Since contains all the iodine of the thyroid gland, and sin all or nearly all the iodine is contained in the collo substance of the thyroid vesicles, thyroglobulin ma be considered a constituent part of this colloi Therefore, since the thyroglobulin is the thyroi hormone, the physiological proof is complete that co loid is the product of the secretion of the glan From the author's experiments he concludes th thyroxin has no sensitizing effect on the nervous sy tem. It does not increase the excitability either the vagus or of the splanchnic. It cannot therefo be regarded as the proper hormone of the thyroi gland.

Pharmacology of Benzyl Alcohol and It Esters.—Charles M. Gruber (*Journal of Laborator and Clinical Medicine,* January, 1925) states th benzyl alcohol and its esters, benzyl acetate and be zyl benzoate, increase the rate of urine secretio when administered intravenously, intramuscularl or intraperitoneally. The mode of action of th drugs in causing this diuresis has not been dete mined as yet.

The First and Last Kink

SIR W. ARBUTHNOT LANE, Bart, M.S., F.R.C.S.,

London

A quarter of a century has elapsed since I described this condition and called the attention of the profession to what I believe to be by far the most important evolutionary structure in the human body which has ever been observed, and one which is productive of very disastrous consequences.

I was led to the discovery and appreciation of the importance of this new development by a study of the changes which the body undergoes when its mechanical relationship to its surroundings is altered from the normal. I found that the human anatomy bears a simple definite mechanical relationship to its surroundings and varies rapidly with any change in that relationship. This I demonstrated in the clearest manner possible in the dissecting room of Guy's Hospital by the examination of the dead bodies of laborers who had been engaged during their lives in various arduous occupations. A careful investigation of the changes which their structure underwent in consequence of the special functions performed showed me that they were so characteristic, so definite and so precise, that from an examination of the anatomy of these laborers I was able to determine with absolute accuracy the life history of the individual, or in other words, the functions he performed during his lifetime.

The laws which I formulated as governing these changes are quite simple, and can be readily understood by a study of these labor conditions.

They are: 1. The skeleton represents the crystalization of lines of force. 2. Pressure produces definite changes. 3. Strain produces definite changes. 4. Without the presence of pressure or strain an old mechanism may be altered or an entirely new one developed. The resulting changes develop to meet the altered mechanical relation of the individual to his surroundings and economize the expenditure of nerve and muscle energy.

The principles which govern the mechanical relationship of the organism to the gastrointestinal tract, which is inside the body, differ in no particular from those that influence its behavior in its mechanical relationship to surrounding objects. *Precisely* the same laws apply in both instances.

The consequences which result from the habitual overloading of the end of the large bowel with at least twenty-four hours' accumulated contents (a condition which is practically universal in our state of civilization and is recognized as being normal) are met on the part of the organism by an attempt to control the excessive dilatation, distention and elongation of the portion of the intestine which is affected by that accumulation. The effort to establish this control is usually more or less successful, the degree of success attained varying with the vitality of the individual. The attempt to control these changes consists in the formation of acquired firm strong bands or membranes simulating peritoneum in appearance. These develop along the lines of strain on the under surface of the mesentery. They gradually secure, contract, and shorten up the mesentery of the iliac colon and finally grip the bowel itself, rotate it on its longitudinal axis and eventually fasten it to the floor of the iliac fossa. The alteration in the functioning of this portion of the intestine which results from the formation of these bands and their mechanical effect upon the mobility of the intestine lead to a corresponding degree of interference with the passage of material through the anchored and obstructed bowel. In civilization the consistence of the contents of this portion of the large bowel is almost always firm and may be often quite hard. This fact again increases still further the difficulty which is experienced in the passage of the fecal matter through the obstructed segment of bowel. In respect to this factor I need hardly recall to you that cancer of the large intestine is eight times more common in the left side of the abdomen than it is in the right side.

Here I would again remind you of another law which I have formulated, namely, that all changes that ensue in the body from an endeavor on the part of the organism to establish a mechanical relationship to abnormal surroundings at first serve a useful purpose, but later tend to shorten the life of the individual. In no instance is this law so true and so clearly illustrated as it is in the case

of what I call the first and last kink. The effect upon the entire gastrointestinal tract is in the first instance simply mechanical. Later it results in the contamination by septic organisms of the nutrient material dammed back and stagnating in the small intestine and stomach and in the terrible sequence of the innumerable morbid sequelæ which ensue in consequence of these mechanical and toxic conditions. When I first called attention to this kink and its consequences, the less observant and more conservative section of the profession denied their existence, and some isolated members, with that lack of courtesy which is so often associated with a corresponding want of comprehension, asserted that the kinks did not exist in the patient's body, but were present only in my brain.

The more intelligent section of the medical profession looked for and investigated the several kinks I had discovered and finding them began by debating their origin. Some believed that they were produced by inflammation, since they could not conceive an acquired band or adhesion arising in any other way. Others considered that they were congenital. Many observers, while recognizing them, were of the opinion that they did not exert any control over the passage of the contents through the anchored bowel. The simple manner in which they come about was not realized, for the obvious reason that the definite changes which the body undergoes when its mechanical relationship to its surroundings are altered from the normal had received little or no attention from the profession.

While in a considerable proportion of cases the organism has sufficient vitality to form these bands and to effect an obstruction limited to this area, in a number of feebler subjects, owing to a want of formative capacity, either no bands are developed or they are not sufficiently strong and rigid to secure the colon which escapes from their controlling influence. In consequence, the lower bowel becomes enormously elongated and distended. The puddling in the pelvis of this elongated and dilated distal portion of the colon produces a degree of obstruction to the passage of solid contents through it which is increased by straining in the effort to expel the motion. It is important to realize that the obstruction so produced is often much greater than that brought about by the limited and localized obstruction brought about by the acquired bands forming the first and last kink. The consequences of this type of obstruction differ definitely from those produced by the kink, in that throughout the length of the proximal intestinal tract little or no effort is made to control the elongation and distention of the colon, small intestine, and stomach, so that the ulceration and cancer of the large bowel, duodenum, and stomach, so common in the case of the first and last kink, due to a definite local constriction, do not occur. On the other hand, in this type, which may for convenience be called the atonic variety, the infection of the food supply which is accumulated in much greater quantity in the elongated dilated bowel, the consequent intestinal autointoxication and the changes resulting from it form a much more marked feature. All the mechanical changes I described have been confirmed radiologically by Dr. Jordan, who has studied the subject so closely for many years.

I need hardly again remind you of the disastrous sequelæ of the obstruction of the colon, either by the formation of bands or by an excessive elongation of its terminal segment. Briefly, they are inflammation of the mucous membrane of the tract ulceration, first simply septic and later often can cerous at the several areas exposed to constan impact or strain, infection of the intestinal contents the contamination of the food supply of the body the flooding of the circulation with organisms toxins and other poisonous bodies and the deterio ration of the cells of every tissue in the body, ren dering them liable to the invasion of the organism of innumerable diseases. As the result of m observations, which have now extended over man years, I am exceedingly impressed by the sequenc of cancer and intestinal stasis. In my opinion thes are two factors in the causation of cancer as w see it in civilization, namely, the mechanical an the toxic.

I have observed cancer imposed on the mechanica and toxic results of chronic intestinal stasis so fre quently that I am convinced that the sequence i not a mere chance.

I have been equally impressed by the absenc not only of cancer, but of all the other direct an indirect results of stasis, as we see them in civili zation in such communities as do not suffer fro chronic intestinal stasis.

TREATMENT

The principles governing the treatment which now adopt in these several conditions differ in n detail from those I formulated twenty-five yea ago.

In the milder cases of obstruction the lubricatio of the canal and the consequent softening of th intestinal contents by the free use of paraffin, o the principle of the flushing tank, are sufficient t meet the disability resulting from a moderate degre of obstruction. Suitable diet, kaolin and belladonn are most helpful adjuvants in that they control th spasm of the inflamed bowel and help to reduce th infection of the food supply.

In more marked obstruction the freeing of th anchored bowel by the careful separation from and from its mesentery of the evolutionary band and the accurate covering by peritoneum of an raw surface which may be left as the result o such separation restore the structure and mobilit of this portion of the bowel to the condition whic existed at birth and permits of the free passage o material through the liberated loop. The results o such a simple proceeding are very often extraord narily striking, the sufferer being frequently restore to health and to the full enjoyment of life with wo derful rapidity.

In most cases this procedure can be effected if th surgeon is perfectly familiar with the arrangemen of the bands, but in a certain proportion, owing t the extent of the acquired adhesions, it is difficu and in some few instances impossible to cover accu rately any remaining raw area by peritoneum. Whe this is the case the bowel is very liable to becom

fixed again by inflammatory adhesions to the floor of the iliac fossa and in consequence does not function properly.

When the obstruction to the passage of the intestinal contents is not due to acquired bands, but to an extreme elongation of the lower segment of the bowel, such disability can only be met by dividing the ileum and introducing it into the side of the pelvic colon or by means of a colectomy. As the elongation and prolapse of the rest of the gastrointestinal tract occurs in the feeble subject and is consequent upon the obstruction in the end of the drainage scheme formed by the very elongated and tortuous termination, to hope to remedy this condition of so-called visceroptosis by sewing up the prolapsed and dilated viscera is obviously futile, since the cause of the accumulation of material with its consequences must remain.

It is not my purpose to discuss at this time the treatment of the ulceration of the gastrointestinal tract, and the other conditions which result from the presence of the first and last kink, but wish merely to call your attention to the enormous importance of recognizing the causal relationship of all the troubles in the proximal bowel and of the deadly and farreaching results of the intestinal autointoxication necessarily associated with it.

In order to obviate the development of the changes I have described, the public must be taught the necessity of evacuating the large bowel three times a day. In the first instances this can only be secured by correct diet and suitable exercise. When the condition of obstruction already exists artificial means must be employed in addition to diet, etc.

The time has come when the medical profession must study the whole question of chronic intestinal stasis thoroughly and, realizing its importance, must endeavor by educating the people in proper habits and diet to obviate this acquired state which may almost be regarded as the normal in civilization.

In view of the generally acknowledged steady increase in the disease and death rate produced directly and indirectly by stasis I feel I cannot urge you too strongly to take the matter in hand in earnest and with the least possible delay.

21 Cavendish Square.

Remarks on Acute Postoperative Dilatation of the Stomach*

FRANCIS REDER, M.D., F.A.C.S.,
St. Louis, Mo.

The postoperative care of a patient in certain instances is just as vital as the operation itself. Sooner or later it is the experience of almost every practising surgeon to have to record as a failure the final results of a particularly satisfactory piece of work because of some error of judgment in the care of the case subsequent to the operation. There is what is termed conveniently a surgical crisis covering a period of about five days for every laparotomized patient. Whatever may transpire during this period usually determines whether or not the end results will prove satisfactory. Certain definite principles of postoperative treatment have become aligned with the development of present day surgery, that an error of judgment, failure to do the right thing at the right time, perhaps an error of omission or one of commission for which the surgeon may have to answer.

However, patients subjected to surgery in which the postoperative attention to detail cannot be questioned have developed sequelæ, the nature of which cannot reflect culpably upon the surgeon. The surgeon can be held accountable only when he has failed properly to interpret important diagnostic guides, or, having correctly interpreted them, his failure to act promptly and fearlessly at the right time.

Except for a few conditions, a postoperative complication is rarely difficult of recognition even in its incipient stage. There is, however, one condition that may arise, which unfortunately is by no means uncommon, whose seriousness and uncertainty of relief cannot be doubted. This condition is an acute postoperative dilatation of the stomach. In endeavoring to garner additional knowledge about this condition a survey of the more recent literature was undertaken. This survey was not particularly illuminating and proved to be more or less an elaboration of certain facts that had been recorded by earlier investigators. Nothing so far has superseded the clearness and instructiveness of Hilton Fagge's description given in 1872-73 in the Guy's Hospital reports. The recognition of this affection in reality dates from this description.

In my surgical experience I can definitely recall ten cases of acute gastric dilatation following abdominal operations. Of these ten patients so afflicted two died, death being directly due to dilatation. One of the deaths occurred rather early in my surgical career and left upon me an indelible impression. What I had gained from this case has proved of inestimable worth for me subsequently. It taught me to exercise the closest scrutiny of my patient during the surgical crisis, it stimulated me in my observations of the slightest suspicious symptoms and it encouraged me to act promptly.

In no condition is prompt action of more vital importance than in acute dilatation of the stomach. Immediate treatment should outweigh all other considerations. When the clinical picture of a gastric dilatation is analyzed the only part free from theory is the existing pathology, i. e., the dilatation of the stomach and the mobile portion of the duodenum. When Fagge wrote his views on this condition in such a classical manner, he scarcely mentioned the etiology. The thoughts he enter-

*Presented before the Southern Surgical Association, Charleston, S. C., December 9-11, 1924.

tained about this particular phase of the condition can probably be surmised when a summary of the present status of opinions from a number of prominent observers is taken into consideration. It can be said that the whole etiological picture of acute dilatation is just as strongly befogged at present as it was at the time of its recognition. A fairly good inference can be gleaned as to how enigmatic the condition has appeared to observers by the various appellations applied to it. The most frequent ones encountered in the literature are: Arteriomesenteric obstruction; arteriomesenteric ileus; gastromesenteric ileus; acute paresis of stomach; postoperative gastric paralysis; gastroduodenal distention; and acute paralytic dilatation of the stomach. These appellations only reflect a difference of opinion as to the nature and cause of the complication. Such differences of opinion are merely personal equations and are rather prone to confuse than to elucidate.

When it is known that an acute gastric dilatation does not necessarily follow an abdominal section, that the condition may complicate an extraabdominal operation, that it may appear after injury or a burn and may evidence itself in the course of a debilitating disease, the etiological solution becomes strongly problematical.

The picture of an acute gastric dilatation presents phases from which at least some understanding can be gleaned as to its cause. Among the postmortem appearances we find of especial interest, next to the enormous dilatation of the stomach and mobile portion of the duodenum, a large quantity of gas, and a fluid, greenish grey or brown in color, that is seldom offensive. It is the presence of the gas and the fluid in such enormous quantities that has shrouded this gastric picture in such mystery.

That there is a certain amount of gas normally in the stomach is well known, just as there is a certain amount of gas in the intestinal tract. It seems to be a necessary medium for the perpetuation of visceral motility. The origin of gas in the stomach cannot be definitely explained. It is assumed to be an admixture of air which has been swallowed, duodenal gas that has been eructated through the pylorus, or, finally, an end product of stomach chemistry or of gastric metabolism.

In conditions where shock, ether and toxins have inflicted their agencies upon the system a reversed peristalsis is not unusual. Such an antiperistalsis would cause duodenal fluids, and perhaps fluids from the more distal intestinal tract, to regurgitate into the stomach. The stomach is not able entirely to relieve itself of this accumulated fluid and the residuum becomes excellent material for saprophytic action. In this manner I believe much of the additional gas is formed during the initial stomach disturbance.

Subsequent stages of acute dilatation depend upon the behavior of the stomach. If there is sufficient tone in the viscus to cope successfully with the irritating influences that are harassing it, restoration to normal will take place. If, however, the stomach is not able to meet successfully the action of certain injurious factors, the clinical picture soon deepens. In acute dilatation, especially in the fatal cases, undoubtedly two factors must be at work. It is my belief that an acute dilatation is more frequent than is assumed. The condition is existing and the patient recovers without the lesion having been recognized. Although it would appear that this morbid change in the stomach could be divided into two forms, a division would only mean that a subsequent complication of a more grave character had arisen. This assumption is apropos in the lethal issues.

An uncomplicated acute dilatation not often terminates fatally. It is the complication, the seat of which is found at the root of the mesentery and involving the fixed portion of the duodenum, that proves to be the dangerous factor. It is here that an arteriomesenteric obstruction with an abnormal resistance is produced which is usually successful in resisting all gastric efforts.

The question I have often put to myself is this: Can an acute dilatation and an arteriomesenteric obstruction exist primarily at the same time? In my reasoning I cannot answer the question affirmatively. I assume with some assurance that an acute dilatation can produce an arteriomesenteric obstruction and that the latter may be the cause of the former.

It is not only in a stomach where there exists a chronic insufficiency, where the disturbances of innervation have been severe, that an acute attack is prone to be superimposed; it is also in a stomach previously healthy; where a sudden motor insufficiency from the action of certain injurious factors may occur which might lead to an acute dilatation.

The condition in its incipiency is an uncomplicated one. When recognized early it can be relieved. If allowed to go unrelieved the intragastric pressure and the associated tension acting upon the already tonically shortened gastric musculature will, through bacterial activity, cause further distention and resultant displacement. This acute dilatation is the more common type and is usually late in manifesting a serious clinical picture.

It is the displacement of the stomach that usually complicates seriously the existing dilatation by forcing the small intestine into the pelvis, producing traction upon the mesentery and thereby causing an obstruction of the fixed portion of the duodenum.

The type of acute dilatation in which the duodenum is primarily involved presents a clinical picture identical with that just described. There is the difference, however: In the duodenal type the symptoms are more severe and are more pronounced at an earlier period. It is the type of acute dilatation which appears almost as soon as the patient has returned to bed. The condition has been appropriately termed arteriomesenteric ileus. It is not as frequent as the paralytic form, but is much more serious. This type of acute dilatation is usually a sequence of an operative procedure involving the removal of a large abdominal tumor. It has also been known to follow a short labor. The provocative cause of the duodenal obstruction can be found in the rapid loss of intraabdominal pressure and the sudden release of support to which the stomach and small intestines were accustomed. Such sudden intraabdominal changes can invite an equally sudden

escent of the small intestine into the pelvis that ıay cause a pull upon the mesentery sufficiently trong to obstruct the third part of the duodenum. ın obstruction of this character when maintained ufficiently long will through toxic action on the ympathetic nervous system impair the gastric tone nd cause an acute dilatation. Such a dilatation t its early stage can be accepted as a decompenation on the part of the stomach in its endeavor to vercome the obstruction.

Death in acute dilatation of the stomach results rom acute toxemia. This reservoir of toxicity is ormed by the part of the duodenum proximal to he obstruction. Among its own glandular secreions it receives the biliary and pancreatic secretions, land products that are unquestionably important actors in the causation of the rapidly fatal conseuences.

It may be recalled here that physiological investiation has established the fact that the stomach pparently absorbs very little. When its digestive vork is done, or when it has none to do, it passes ts contents rapidly into the duodenum, from the illi of which rapid absorption occurs. An experinent by Dr. Edkins (London) to demonstrate this oint consisted in ligaturing the pylorus in a cat. A many times lethal dose of strychnine, a drug o which cats succumb in the smallest dose, was ntroduced into its stomach. For several hours while he pylorus remained ligatured no ill results hapened; however, as soon as the ligature was removed the cat passed into strychnine convulsions.

This is important for surgeons to bear in mind when contemplating an operative attack upon a case of acute gastric dilatation. It is not the stomach that requires drainage, but the obstructed duodenum. This has been repeatedly demonstrated by the failure of a posterior gastrojejunostomy, an advocated surgical measure for this condition.

The clinical findings pertaining to the different phases of an acute dilatation all appear reasonably clear, excepting the enormous amount of fluid with which the stomach is so often encumbered. The evidence suggests that the hypersecretion is caused by an underlying disturbance of gastric innervation. In most cases the distention of the stomach is gaseous; however, in the cases which I encountered enough fluid was repeatedly siphoned off to cause one almost to forget about the gas. The astounding fact is that a deranged action of the hormones with the resultant loss of control of the secretory glands of the stomach could produce so copious an amount of fluid in so short a time. However, the chapter on the secretory function of the stomach is still greatly befogged so that it is not surprising that the cause of this pathological hypersecretion remains somewhat obscured.

When we consider the clinical picture with its syndrome we have one which is so classical that when once seen cannot be misinterpreted even by the casual observer.

The general condition of the patient appears as being serious from the first. He is pinched and careworn and looks as though he has aged suddenly. Collapse is noted in nearly all severe cases. The skin often is cold and clammy, the patient is restless, his pulse is rapid and thready and of poor quality. The eyes are sunken and hollow. Respiration is rapid and shallow, simulating air hunger. Among the earlier symptoms there is a heavy gnawing pain in the pit of the stomach, accompanied by vomiting of large quantities of fluid with very little effort but with no relief. This vomiting at first is of a projectile nature; later, however, as the fluid accumulates in greater quantity and the atony of the stomach becomes more marked, the character of the vomiting changes to the spitting up of mouthfuls of fluid during very short intervals. The systemic fatigue is evidenced by the constantly increasing pulse. The fluid vomited resembles root beer, but it can be greenish grey. In the earlier stages it is seldom offensive. Thirst on account of the rapid dehydration becomes intolerable. There is often a desire to urinate, but the quantity, if any, is very scant. The temperature rarely registers above normal and is frequently subnormal. By inspection and palpation the dilated stomach can usually be demonstrated satisfactorily through an abdominal wall that is free from tenderness and rigidity.

Clear as this clinical picture of an acute gastric dilatation may appear, there are several postoperative conditions the symptoms of which in part bear a close resemblance to those of acute dilatation and might lead to diagnostic error. These conditions are peritonitis, postoperative ileus and internal hemorrhage. Differentiation may be somewhat difficult at the outset of the disturbance; however, with a close study of the condition a definite conclusion should be reached without much delay.

Certain characteristics of gastric dilatation, such as absence of fever, perhaps a subnormal temperature, the absence of abdominal tenderness and rigidity, the frequent and copious vomiting of a regurgitant type, and the distinctive topography of the abdominal distention should prove most helpful factors in clearing up any existing doubt. However, if an uncertainty as to diagnosis still remains, the passage of the stomach tube will cause a temporary disappearance of the distention if the condition is an acute dilatation. For this procedure we are indebted to Kussmaul.

On account of the high mortality rate of this condition, sixty-three per cent. at best, it is apropos to speak of the postmortem appearances. These are in most recorded cases strikingly similar. A hugely distended stomach having the appearance of an enormous ovarian cyst and filling the whole abdomen is the most striking picture. The stomach is sharply bent upon itself and can be likened to a gigantic U with unequal branches. Its walls are thin and the mucosa hemorrhagic. The dilatation rarely involves the stomach alone, but also implicates the duodenum up to the point where the superior mesenteric vessels cross the viscus. This is the fixed part of the duodenum and it is here that the localized constriction with its grave influences has its seat.

There has been considerable controversy about the nature of this obstruction caused by the mesentery which incorporates the superior mesenteric vessels, because not sufficient evidence of a demonstrable character could be found at postmortem.

When we consider that the mesentery is purely a fatty bolster, the superior mesenteric vessels acting only as trabeculæ, it can be readily inferred how an occlusion of a fixed and soft viscus can occur without appreciable damage to its structures.

The condition could be readily likened to a blow on the head with a stuffed club. Such a blow can cause unconsciousness without visible injury to the soft parts. If a similar blow were dealt with a blunt instrument, evidence of damage to the soft structures would be readily discernible in most instances. Furthermore the fact must not be overlooked that an acute dilatation causes death usually in from two to five days. That, however, does not imply that a mesenteric compression has existed for so long a time. From my clinical observations I can assume that death results very quickly after the mesenteric compression has established a complete duodenal obstruction and that in most instances the time factor was too short to produce appreciable pathological changes in the obstructed part of the duodenum.

The treatment of an acute gastric dilatation resolves itself into two exigencies, viz., prompt recognition and prompt action. Inasmuch as the condition must be construed as an emergency immediate treatment must outweigh all other considerations. Siphonage of the stomach as advocated by Kussmaul and the postural form of treatment as advised by Schnitzler become imperative measures. If these two procedures are carried out judiciously, the patient's chances for recovery are augmented. The stomach must be relieved of its contents. Inasmuch as this viscus will refill rapidly, repetition of the siphonage must be resorted to at frequent intervals and continued until further accumulation has ceased. In one of my cases siphonage had to be continued for three days.

It must be borne in mind that in some cases the distention of the stomach may be so enormous that the tube will not reach the bottom of the viscus. Under such conditions there could be no siphonage. When such a state is suspected the patient's hips must be elevated to aid displacement of the fluid. The postural form of treatment is as important as the siphonage. Its theory appears sound especially when the mesenteric compression of the duodenum features as a serious factor. The patient is placed upon the abdomen, inclined a little to the right side, with the hips gently elevated. With a patient in this posture the pull upon the mesentery will be relieved or greatly lessened. With these attentions additional ministrations to relieve shock and to sustain the patient must be given.

SURGICAL TREATMENT

I wish I could feel more encouraged about surgical measures for an acute gastric dilatation. My experience with postoperative paralytic ileus has been so unfortunate that I cannot but harbor a feeling of apprehension in contemplating a surgical attack upon an acute gastric dilatation. It would appear that in the early cases life can be saved by siphonage. In those cases where the condition has not been recognized early, I can only entertain the greatest doubt for any surgical treatment. The patient usually is in such a severe shock that an operation would necessarily increase the amount of existing shock.

There are some cases, however, that present certain indications for operative intervention which are at least theoretically logical; however, the mortality where an operative measure was undertaken by most excellent surgeons has been so high (eighty-five per cent.) that one cannot but feel that the condition is not one for operation.

Diaphragmatic Hernia*

JOSEPH J. WELLS, M.D.,
New York

True diaphragmatic hernia is a surgical condition that is rarely seen, and still more seldom diagnosed before operation. For a proper appreciation of its etiology, pathogenesis, and the failure of making a preoperative diagnosis, an anatomical review is necessary.

The diaphragm is a fibromuscular partition separating the thoracic and abdominal cavities. It is a domeshaped muscle which attaches to the distal margin of the thorax and upper lumbar vertebræ. The central portion is an aponeurosis and is known as the central tendon. The diaphragm is innervated by the phrenic nerves. It is not a complete partition, inasmuch as it is pierced by bloodvessels, nerves, and the esophagus. These structures pass through or are formed by the three crura of the diaphragm, which are subdivisions of its lumbar portion.

The important openings or perforations are: 1. That by the inferior vena cava, which passes through the central tendon, slightly to the right of the midline. 2. That by the aorta and thoracic duct, which is formed by the separation of the two medial crura. 3. That by the esophagus, which is formed by the division of the right crus, but sometimes is formed by the right and left crura, the esophagus passing between these two structures. 4. That by the superior epigastric vessels, which pass between the sternal and costal portions of the diaphragm.

The diaphragm has two serous surfaces, thoracic and abdominal. Its thoracic surface is covered by pleura, except the central portion of the central tendon, which is attached to the pericardium. The abdominal portion is covered for the most part by peritoneum.

A review of the literature on the subject of diaphragmatic hernia reveals about twelve hundred

*Read at the Monthly Conference of the Surgical Staff of the New York Post-Graduate Hospital and Medical School, Service of Dr. Charles Gordon Heyd, March 2, 1925.

cases, about one third of which were reported since he beginning of the World War. Most of these atter cases, however, were not true hernia, but, as vill be explained later, prolapsus of the abdominal viscera through an injury to the diaphragm.

For simplicity, diaphragmatic hernia may be livided into two classes, true and false, and also nto congenital and acquired. The false herniæ are always produced by trauma, with resulting injury to he diaphragm, and prolapse of the intestine. These herniæ are not at first covered by a sac, but later on the prolapsed viscera become covered by a pseudomembrane and resemble true hernia. The diagnosis between the two conditions is very difficult in long-standing cases. The history of trauma will aid in its differentiation.

True diaphragmatic hernia is covered by a peritoneal sac. In the older cases, due to the growth of the hernia, the overlying pleura is pushed forward and therefore the hernia is covered by two serous sacs, peritoneal and pleural. There is a third variety, which, however, cannot be classed with the hernia, but which is often confused with hernia. It is mentioned for the sake of completeness, and also as an aid in the differential diagnosis. This third variety is known as eventration. It is a congenitally high position of the diaphragm, and unless one is careful, he might be misled into calling it a diaphragmatic hernia. This will be taken up later under the heading of differential diagnosis.

The etiology and pathogenesis of diaphragmatic hernia in traumatic cases is obvious and readily understood. A rent occurs in the diaphragm and through this defect the abdominal viscera are gradually sucked into the thoracic cavity by reason of the negative pressure of the pleural sac. At first in these cases the herniæ are rarely covered by a sac, but later, due to irritation, a pseudosac is formed. Anatomically, the condition can hardly be differentiated from true diaphragmatic hernia. If the rent is a comparatively small one, incarceration of the prolapsed viscera may occur, with perhaps resulting gangrene and perforation. This is an exceedingly dangerous complication even if operation be performed at once, on account of the probability of both peritonitis and empyema resulting.

True acquired diaphragmatic herniæ occur at the sites of perforation of the diaphragm. These sites have been enumerated under the anatomical discussion. The condition manifestly is very rare on the right side, owing to the protection afforded by the right lobe of the liver.

Hume has attempted to define the types of congenital diaphragmatic hernia and to indicate their probable pathogenesis. He describes four types: 1, through the hiatus pleuroperitonealis; 2, through the dome; 3, through the esophageal orifice, and 4, hernia due to the absence of the left half of the diaphragm. Type one is the most common, if fetal cases are considered. Hume suggests that the intestine follows the lung through the hiatus when the former leaves the celoma. The frequency is greater on the left side. Type two occurs as a true or a false hernia. Pressure of the abdominal viscera may produce a hernia at some weak point in the dome. Type three is due to the failure of the normal caudal migration of the stomach. If the embryology of the parts as described by Hume are accepted, hernia through the esophageal orifice cannot be regarded as acquired. Type four is not infrequently found in the fetus and is incompatible with life.

The diagnosis of diaphragmatic hernia may be made clinically or with the aid of the roentgenologist. A clinical diagnosis alone, proved by operation or postmortem, has seldom been made. The use of the x ray has been a wonderful aid in the diagnosis of this condition. However, in routine roentgen chest examination, diaphragmatic hernia has often been overlooked or wrongly diagnosed. The best diagnostic results have been obtained in those cases in which it was suspected clinically and then proved roentgenologically. It is important to make a diagnosis of diaphragmatic hernia, because if unreduced it may become strangulated and lead to the death of the patient. Diaphragmatic hernia must be differentiated from elevation of the diaphragm caused by a very large stomach, dilatation of the colon, ascites, pregnancy, and true eventration. Symptoms caused by diaphragmatic hernia vary considerably. Gastric symptoms are quite common and often the condition is wrongly diagnosed as gastric ulcer or carcinoma.

The records of the New York Post-Graduate Hospital reveal but one case of diaphragmatic hernia which came to operation. This case was wrongly diagnosed as a perforating ulcer with possible malignant degeneration. The roentgen examination of this patient had revealed a markedly deformed stomach with cardia and pylorus at the same level and an undue elevation of the left diaphragm. In spite of these roentgen findings and on the basis of the clinical history, which was almost classical of penetrating gastric ulcer, a preoperative diagnosis of ulcer was made.

The heart and cardia are often displaced to the opposite side and there may be an area of tympany in the thorax. Respiratory embarrassment is often manifest. It is in these cases, in which the clinician strongly suspects the presence of a hernia, that the roentgenologist is able to demonstrate it. Without the cooperation of the clinician, the condition is often overlooked by the roetgenologist. The presence only of solid viscera in the hernia would naturally render it more difficult for the roentgenologist to arrive at the correct diagnosis.

Congenital hernia due to a large diaphragmatic defect and prolapse of part of abdominal viscera, often leads to the death of the infant soon after birth. If operation is undertaken the prognosis is bad since the patient presents a grave operative risk.

The other varieties are amenable to operative treatment, if undertaken before incarceration or strangulation has occurred. If this latter complication has taken place, the case presents an extremely grave outlook with or without operation, on account of the danger of peritonitis or empyema. The best method of approach is the combined transpleural and transperitoneal route, after preliminary temporary blockage of the phrenic nerve. Opening the pleural cavity overcomes the negative pressure and allows of easier reduction of the herniated viscera.

Chronic Irritable Colon*

JOHN W. VISHER, M.A., M.D.,
Twin Falls, Idaho

Chronic irritable colon is a functional disorder of the large intestine characterized either by refractory constipation of the spastic type, continuous mushy or watery stools, or alternating constipation and diarrhea, together with local and general symptoms of a rather varied nature. It includes many cases usually diagnosed as spastic constipation, as chronic colitis, as nervous diarrhea, and as intestinal and gastric neuroses. The term chronic irritable colon was suggested by Brown (1) because it seemed to him irrational to call this condition a colitis when no inflammatory changes are present.

INCIDENCE

Previously I (2) have called attention to the frequence of this condition in neuropsychiatric cases. Because of the confusion in nomenclature and because of the frequency with which it is overlooked, statistics are not available which throw much light on its incidence in medical practice. In my experience, however, chronic irritable colon has been met with three times as often as gastric carcinoma and five times as often as peptic ulcer. It is unquestionably the commonest gastrointestinal condition I am called upon to treat.

PATHOLOGY

Since this syndrome has been defined as a functional disorder, it is apparent that in an uncomplicated case, no colonic pathology is found. In the severe cases there may be, however, mild inflammatory changes in the mucosa. The colon is often spastically contracted either in certain parts or as a whole.

ETIOLOGY

The most important etiological factor is the increased irritability of Auerbach's plexus. This irritability of the intrinsic nervous mechanism of the colon is probably inherited in most cases, though a normal or even a sluggish plexus may be made irritable if insulted for a sufficiently long time. Many people probably have somewhat irritable Auerbach's plexuses, but have no serious symptoms therefrom, as they have learned by experience their dietetic, medical and hygienic limitations. When other etiological factors come into play, the irritability is markedly increased and the symptoms described hereafter appear.

The most important contributing factors are the enema and cathartic habits, chronic colonic obstruction, improper dietary habits, debilitating diseases, chronic appendicitis, chronic cholecystitis and ureteral pathology.

The enema and cathartic habits are mentioned first because they are perhaps the most important. They are further discussed under treatment.

Chronic colonic obstruction due to ptosis, kinks, stricture or new growths of the large bowel, peritoneal adhesions, pelvic tumors, pregnancy, anal spasm or stricture, may, by preventing the normal emptying of the bowel, help to bring about the syndrome of chronic irritable colon. The damming back of the bowel contents leads to putrefaction and liquefaction of the fecal mass, with the production of an irritating, malodorous stool. Moreover, such obstruction often leads to the enema or the cathartic habit.

Improper dietary habits, especially the ingestion of large amounts of fried foods, rich pastry, and too coarse or poorly cooked foods, are important etiological factors. Thorough mastication is so important that this syndrome often develops in individuals who have lost most of their teeth.

Sufferers from the debilitating diseases, such as tuberculosis, nephritis, carcinoma, and diabetes, not infrequently have symptoms of chronic irritable colon which clear up when the underlying disease is under control. This is especially true of pulmonary tuberculosis.

Chronic appendicitis, chronic cholecystitis, and to a lesser extent other foci of infection, such as apical abscesses and sinus or tonsillar infections, are recognized etiologic factors. The evidence is strongest against the appendix. Deaver (3) has pointed out that long standing chronic appendicitis may even cause a true inflammatory colitis.

Another factor of lesser importance is discussed by Goldschmidt and Mulleder (4). They report a series of cases apparently of this syndrome following extensive operations on the stomach. The probable explanation is that these plastic operations caused too rapid emptying of the stomach and upset the nicely timed mechanism of gastric and intestinal digestion. The bowel disturbances in achylia gastrica, as pointed out by Stockton (5), are probably of the same origin, as the undigested food is propelled rapidly to the colon, where it is attacked by the fermentative and putrefactive bacteria with the formation of an irritating stool.

Biliary obstruction, pancreatic deficiency, or chronic enteritis with deficiency of the intestinal enzymes may also result in incomplete digestion in the small bowel. In some cases the carbohydrates alone are undigested and a fermentative diarrhea results. In some others, the proteins are not digested and a putrefactive diarrhea results.

Another somewhat less recognized cause of the syndrome of chronic irritable colon has been emphasized by Hunner (6), namely, ureteral stricture and its associated pathology. I have had several cases illustrating this factor in my series.

In persons having irritable Auerbach's plexuses many minor factors will precipitate an attack of diarrhea. These include dietary indiscretions, menstruation, grief, fright, anxiety, mental stress and overfatigue. Chilling of the body surfaces and minor systemic infections, such as colds and bronchitis, are also important factors. In fact, in a severe case any lowering of the bodily resistance may precipitate an attack.

*From the Department of Internal Medicine, Twin Falls Clinic.

COURSE

The course is an extremely chronic one, often with long remissions or at least comparative freedom from symptoms; in fact, it probably accompanies many individuals from the cradle to the grave. It is likely that the extreme difference between infants in their reaction to the same dietetic regimen may be explained, in part at least, by inherent differences in the excitability of the nervous mechanisms of their gastrointestinal tracts. It is met with not infrequently in young children who have been improperly fed. Diarrheic attacks are often confined to periods of lowered physical resistance, or following feast days. In adult life these individuals may do well when living at home where their selfdiscovered dietary limitations are known and adhered to, but if circumstances make dieting impossible, their sufferings begin. The degree of invalidism resulting depends largely on the type of personality of the sufferer, and on his experiences with the medical fraternity. If his symptoms have been called "imaginary" or "due to nervousness," he is likely to become neurotic, while if they are understood and properly treated he will be more apt to face his difficulties stoically.

SYMPTOMATOLOGY

For purposes of description, the symptoms of chronic irritable colon may be divided into three classes: firstly, those referable to the colon itself; secondly, those resulting from reflex effects on other organs; and thirdly, those due to absorption of toxic substances.

Of the first class, perhaps the most frequent symptom is diffuse abdominal discomfort, present practically continuously but much aggravated by a diarrheic attack. It may be severe enough to be described as abdominal pain by the patient, and it is often most marked over the splenic flexure or the cecum. The discomfort is worse just before and just after defecation. It is relieved somewhat by the passage of flatus, of which there is usually an abnormally large amount. Another symptom frequently complained of is intestinal cramps. These are often more severe just before a bowel movement, but not necessarily so. The act of defecation may be followed by mild tenesmus, and a feeling of incomplete evacuation. Actual filling of the colon with gas may lead to marked distention with pressure symptoms such as palpitation, angina, or dyspnea.

The chief reflex symptoms are gastric and include heartburn, attempts at belching, and an uncomfortable feeling of fullness after even a small meal. Many state that they feel hungry before they start to eat, but after taking a few mouthfuls, they feel so full that they can eat no more. Some patients have nausea and more rarely vomiting during the diarrheic attack. So important are the gastric symptoms that many patients come to the physician with a selfmade diagnosis of dyspepsia or chronic gastritis.

In attributing the symptoms about to be described to toxic absorption from the bowel, I realize that I am running the risk of being dubbed oldfashioned. No one can condemn more strongly than I the too frequent diagnosis of intestinal autointoxication, especially when it is made without a thorough search for other causes of the symptoms. That toxic absorption does not occur from the normal bowel, or from the atonically constipated bowel, is now conceded by most internists. The experiments of Donaldson (7) on voluntary constipation in healthy men seem to indicate that many of the symptoms of constipation are reflex. If, however, sufficient damming back occurs to permit regurgitation of fecal matter into the ileum, or to promote excessive putrefaction in the upper colon, absorption of toxic materials seems at least theoretically possible. Certainly, when there is either a continuous foul diarrhea, or alternating constipation and diarrhea, toxic absorption is possible. The diarrheic stool in these conditions is so irritating that defecation is often accompanied by burning and scalding about the anus. Such a stool might conceivably cause sufficient temporary damage to the epithelial cells of the mucosa to cause them to permit the absorption of toxic products in much the same way that intestinal obstruction in the small bowel permits the absorption of histamine, as has been demonstrated by Dragstedt (8). Donaldson himself says, "I have no disposition to deny that cases of autointoxication of intestinal origin do exist," and states that Alvarez and Bainbridge (9) believe that it is present in cases of persistent diarrhea. Von Noorden (10) is of the same opinion. The work of Luckhardt (11) and his coworkers on the etiology of tetany supports strongly the theory of toxic absorption from the intestine.

The chief symptoms which may be attributed to toxic absorption are headache, general malaise, neuralgia, arthralgia, myalgia, precordial pain, urticaria, acne and other skin conditions, retinitis, tachycardia, fatigability, loss of energy, insomnia, and other neurotic and neurasthenic manifestations. Elsewhere I (2) have described somewhat at length the psychoneurotic manifestations of sufferers from this disorder and explained the pathogenesis of their neurosis. In the same place are several case reports illustrating the symptomatology and complications.

PHYSICAL FINDINGS

The skin often has a subicteric, "muddy" appearance not unlike that seen in malignancy. The tongue is usually heavily coated, and the breath is often foul. In the more severe cases, there is marked tenderness over the entire abdomen, but in the ordinary case only the colon and the abdominal plexuses are tender. Sometimes only a part of the colon is tender. Frequently it is found to be spastically contracted. Proctoscopic examination is usually essentially negative. Tenderness over the nerve trunks is a frequent finding.

LABORATORY FINDINGS

Laboratory examinations reveal, as a rule, a normal blood picture or only a moderate anemia. Gastric analysis usually is normal, although, as pointed out by White in an excellent article (12), there may be either hyperacidity or hypoacidity. Fluoroscopic and radiographic studies may show no gastrointestinal pathology whatever. They often show delay in the emptying of the colon. The colonic shadow may show a narrowing due to spasticity, and the associated pathology is often demonstrated by radiography.

The stools (13) usually show characteristic changes. A word of caution is necessary, however,

as the stool at times, even in a severe case, may be nearly if not quite normal. Repeated examinations are necessary and a careful history is more important than fecal analysis. The character of the stool varies widely in different cases and in the same case at different times. It may consist of very hard, small masses, or it may have a watery consistency and contain much mucus. Between these two extremes all possible gradations are found, except that a large, formed stool is a rarity. The most frequent is the "mushy" stool containing some mucus, which, however, is only mushy in the jar. When passed into an ordinary closet bowl, the " mushy" stool often forms long thin ribbons, or shorter pieces exploded by gas. Few physicians know the gross appearance of a normal stool. Ignorance in this matter is apt to lead to many errors in diagnosis. Microscopic examination reveals no pus or blood, unless there are complicating conditions. Undigested food may be present if the stool is loose. Staining by Gram's method is important, for in the fermentative type, gram negative organisms predominate, while in the putrefactive type gram positive organisms are more numerous. The reaction to litmus is acid in the fermentative type, and alkaline in the putrefactive type.

DIAGNOSIS

The diagnosis of chronic irritable colon is not difficult as a rule, but a thorough physical examination with especial attention to the gastrointestinal tract should be made in each case, as this syndrome may accompany and mask serious organic disease such as appendicitis, cholecystitis, carcinoma of the stomach or bowel, ulcerative colitis, intestinal obstruction, pernicious anemia, ureteral stricture, pulmonary tuberculosis, etc.

A complete discussion of the differential diagnosis is obviously beyond the limits of this paper. Two functional disorders of the colon will be mentioned, however, to assist in differentiating this syndrome from closely allied conditions, namely, atonic constipation and mucous colitis.

Atonic constipation is not accompanied by marked abdominal discomfort, or signs of toxemia. The stools are large and formed, and diarrhea never occurs. Radiographic study shows dilatation rather than narrowing of the bowel.

Mucous colitis is characterized by the periodical expulsion of large amounts of thick, tenacious mucus. In its typical form, it is an uncommon condition of obscure etiology. Its treatment, however, does not differ materially from that indicated in chronic irritable colon, so that exact differentiation is not required.

TREATMENT

The first step in the treatment should obviously be directed against the organic etiological factors. If systemic disease exists, it should be vigorously treated. Surgery is often necessary, but it does not cure—it only makes a cure possible. Appendectomy, cholecystectomy, or radical cure of colonic obstruction, must be followed by medical treatment. The neglect of adequate postoperative medical treatment is responsible for many clinical failures following operations that are distinctly indicated in themselves.

The next step in the treatment is to eliminate each of the other important etiological factors. The abuse of cathartics probably leads to more invalidism than the abuse of morphine. Certainly there are many more cathartic addicts than morphine addicts, and it sometimes seems that it is as hard to break the former of the habit as it is the latter. B. W. Sippy often made the statement that he had not used a cathartic in the treatment of constipation for twenty years, and it is certain that there would be far less intestinal invalidism if every physician would follow his example. The routine use of laxatives before and after operations has been wisely attacked by Alvarez and others. Fantus (14) in his little book entitled *Useful Cathartics,* which should be on every practitioner's desk, teaches a very sane policy. After condemning the indiscriminate use of cathartics by the laity, he says, "let us be sure our hands are clean. A cathartic prescribed by the physician is no less liable to produce a cathartic habit than one taken by the patient on his own account. Indeed, when the physician prescribes the remedy, the patient feels all the more certain that it is good for him, and he is likely to keep taking it. After all, the medical practice of the laity reflects the past practice of the medical profession."

Of almost equal importance is the correction of dietary errors. A complete discussion of the effect of various foods on the gastrointestinal tract in health and disease would require many pages. I can only outline briefly some of the more common dietary factors of importance in the syndrome of chronic irritable colon. Fat is perhaps the chief offender, especially when used in frying or as shortening. Butter and vegetable oils are somewhat less harmful. Roast pork, sausage and pork chops seem especially pernicious. In frying or when used as shortening, the fat forms a coating around the food particles, which makes digestion in the stomach impossible, and in the small intestine difficult and incomplete. When this material reaches the colon, it is attacked by bacteria and the fats are split up into the irritating fatty acids. Neutralization and saponification of these fatty acids, which normally take place in the small intestine, are impossible in the colon. The destruction of the fatty coating liberates the carbohydrates and protein which in turn are attacked by fermentative and putrefactive bacteria with the formation of carbon dioxide, hydrogen sulphide and other gases, indol, skatol, histamine, etc. These irritating and toxic substances may act as drastic cathartics, and cause purgation. If immediate evacuation does not result, absorption is likely to follow with resultant symptoms of socalled autointoxication.

Inadequate cooking is another important factor. The walls of all vegetable cells are made up of cellulose which is burst by thorough cooking and the contents are exposed to the action of the digestive juices. Inadequate cooking leaves a number of the cells unaffected and since cellulose is not normally digested by the gastric or intestinal enzymes these cells reach the colon intact. The cellulose is there attacked by the fermentative bacteria, and the cell contents are exposed to bacterial action. Raw food is often less irritating than partially cooked food probably because it passes through the entire gastrointestinal tract without digestion or destruction by bacterial action. The cell structure differs greatly in different vegetable foods, which perhaps accounts

for the great variability in the length of cooking necessary.

Not only the quantity and distribution of cellulose, but the chemical properties of the cytoplasm are of great importance. Let us compare, for example, cabbage and spinach. Cabbage requires prolonged cooking, and its ingestion even in small amounts is always followed by untoward symptoms in a sufferer with chronic irritable colon. Spinach, on the other hand, requires comparatively little cooking, and is very well borne when taken in the same quantity. Squash is well borne, while navy beans cause a marked disturbance.

The effect of fruit on the bowel depends chiefly on its chemical constituents. In the process of ripening, most of the starch and cellulose is converted into sugar, so that cooking is needed chiefly to soften the fruit and to assist in its thorough mastication. Mastication of raw fruits is seldom complete, so that the skin and large masses of the pulp reach the colon undigested. There they are attacked by bacteria and irritating substances may result. It is well known that fruit juices vary considerably in their laxative effect. Apple juice, grape juice, watermelon juice, etc., are laxative, while blackberry juice is distinctly constipating. The effect of a given fruit, therefore, depends on several factors: firstly, whether the skin and seeds are swallowed; secondly, whether the pulp is finely divided; and thirdly, whether the juice has a laxative or costive action.

The exact management of a sufferer with chronic irritable colon depends upon whether he is having continuous diarrheic or mushy stools, alternating constipation and diarrhea, or continuous constipation. It is important to recognize that these are different stages of one process, for a sufferer may pass through all of these forms in a year. In certain cases, however, one type seems to predominate for a long time. Not infrequently following treatment for the diarrheic type, the spastically constipated type developed. In these instances the patient seems to lack the necessary courage to increase his diet adequately, fearing the return of the diarrhea. In still other cases the stools will be normal for long periods, with brief attacks of diarrhea caused by the associated pathology or lowered physical resistance or dietary indiscretions.

TREATMENT OF DIARRHEIC FORM

When continuous diarrhea is present, the patient should be put to bed and dry heat applied to the abdomen. The diet should consist of foods leaving no residue, and as bland as possible. Thin gruels of farina, rice or barley, crackers, and fat free broth may be given at frequent intervals. This diet should be continued until the diarrhea is checked, and only one or two stools are passed a day. Even if the stool is still mushy, the addition of certain soft foods is indicated. The first to be added are the simple puddings, such as those made with farina, cornstarch, tapioca and rice. Custards, soft boiled or coddled eggs and crisp toast may be added cautiously. Still later lean, well cooked roast beef or mutton, or stewed chicken may be added followed by the purees of potato, celery, tomato and spinach. Some authors describe fermentative diarrhea and putrefactive diarrhea and recommend treating the former with a carbohydrate free diet and the latter with a protein free diet. This is very useful in certain cases but usually complete elimination of neither carbohydrate or protein is necessary. The symptoms and character of the stool must be the guide in increasing the diet and in allowing the patient more liberty.

Medicinal aid is usually not necessary or advisable. In obstinate cases I use Sippy's powder consisting of equal parts of calcium phosphate, calcium carbonate and bismuth subnitrate, in one or two teaspoonful doses every four hours. Von Noorden (10) recommends atropine in from .001 to .003 gram daily, but others have found it uncertain in action. It is perhaps of greatest assistance in the spastic type, when cramping is very troublesome. The use of opium or of tannic acid preparations by mouth is usually harmful and should be avoided. The use of sedative drugs, such as the bromides, the hypnotics and codeine, may be of assistance for a short time in neurotic cases. It must be recognized that drug therapy is palliative, while dietary management is curative.

TREATMENT OF PATIENT WITH MUSHY STOOLS

The treatment of the patient with mushy stools includes hygienic and dietetic measures. The use of drugs is entirely unnecessary as a rule, and their prescription is apt to detract unduly from the importance of dietary measures. The patient should lead a quiet, well ordered life, avoiding overfatigue, excitement and exposure. Plenty of sleep is an essential and a short rest after meals is very helpful. Complete cessation from work is not necessary as a rule. The fact that the patient has not diarrhea indicates that he is partially able to cope with the situation without dietetic help. If, however, he fails to improve under treatment while at work complete rest should be ordered. A careful inquiry into the patient's dietary habits should be made, and the offending articles of diet eliminated. Frequently this is all that is necessary. In other cases, giving the patient a diet sheet and explaining carefully the rationale of the treatment and briefly outlining the reasons for eliminating certain articles of food from his diet will be sufficient. The accompanying diet sheet (Table I) with individual modifications, is used in this clinic.

The patients with alternating constipation and diarrhea usually respond to the same treatment as those with mushy stools, though a somewhat more laxative diet may be necessary. The diet should not be too strict during the temporary diarrheic attacks, lest constipation again return. It is necessary to secure a bowel movement every day in these cases. This can be brought about by dietetic management alone if supervision is close enough. The patient may be instructed to take one half to two ounces of mineral oil at night if the bowels have not moved that day, or if the movement has been very dry and hard. The next morning if the bowels do not move a rectal injection of one half to one pint of normal saline may start the movement. Petrolagar, in one to two tablespoonful doses, once or twice a day is often helpful.

SPASTIC CONSTIPATION

In continuous spastic constipation, the diet should be moderately bland, but must contain a large

TABLE I.

Fluids:	Large amounts of water; milk and cream; weak cocoa, tea or coffee.
Soups:	Cream of tomato; puree of potato, pea, corn, celery or asparagus; meat soups if not greasy.
Bread:	Crackers, white bread and toast. No bran or graham bread.
Cereals:	Farina, rice, oatmeal and corn flakes.
Eggs:	Two or three daily in any style except hard boiled or fried.
Meat:	Chicken, turkey, baked fish, lean beef or lamb very well cooked and carefully masticated.
Vegetables:	Potatoes, sweet potatoes, spinach, young beet greens, squash, lettuce, tender asparagus, stewed or raw celery, tomatoes cooked or raw, very tender string or wax beans, carrots, turnips. All vegetables must be well done.
Fruits:	Stewed prunes, baked apples, apple sauce, stewed peaches, stewed pears, stewed apricots, stewed figs, stewed plums, fresh oranges, grapefruit, strawberries, raspberries, blackberries and musk melon. Eat small quantities of all the above except prunes and oranges, which can be had liberally.
Desserts:	Rice pudding, tapioca pudding, farina pudding, bread pudding, cornstarch pudding, custards, jello, simple cookies and light cakes, (sponge cake, etc.). Ice cream and sherbets may be tried cautiously. Honey and jelly in small quantities.
Misc:	Macaroni, spaghetti, cheese, butter, peanut butter.

AVOID THE FOLLOWING

All fried foods and all food containing shortening; all highly seasoned foods; candies; nuts (including peanuts), watermelons, grapes, bananas, beans, peas, cabbage, beets, onions and pork.

CONSTIPATION

The fruits and vegetables and other laxative foods should be taken in just sufficient quantities to produce one or two normal bowel movements a day.

Never take cathartics or large enemas.

---

residue. Too coarse food should be avoided. The indiscriminate prescribing of "bran, coarse vegetables and plenty of fruit" for every constipated person leads to much intestinal dysfunction. The use of coarse foods may be useful in the treatment of atonic constipation, and of constipation in some cathartic addicts, but is certainly pernicious in most cases of spastic constipation. The foods mentioned in the diet list given above are well adapted for cases of spastic constipation. The laxative foods in this list should be taken in very liberal quantities. Spinach and prunes are especially valuable as they are bland and nonirritating even in large quantities, but efficient in overcoming this type of constipation. Defecation at exactly the same time each day is very essential. The patient should be taught to set apart a certain half hour during the day, for defecation. Reading while at stool is helpful as it often leads to relaxation. If at the end of the half hour the attempt is unsuccessful, the injection of one half pint (250 c. c.) of normal saline solution will often suffice to start the movement. Drinking one or two glasses of hot water on arising is often beneficial. The patient should also be instructed to drink plenty of water during the day.

The use of other than dietary and hygienic measures is not necessary in spastic constipation provided the patient is under close observation and cooperates completely. The measures suggested for a relief of constipation in the cases with alternating constipation and diarrhea may be used here if necessary. Petrolagar is especially valuable in some cases of spastic constipation. The use of retention oil enemata is also valuable. No medicated enemas or other laxatives should be used, and the patient should be taught that constipation is less harmful than catharsis.

In general, it will be seen that the treatment of chronic irritable colon requires prolonged dietary management, and much patience on the part of both the physician and the sufferer. The patient must ultimately learn his dietetic limitations, and must become sufficiently conversant with the principles outlined in this paper to keep his bowels normal and to be able to treat himself when suffering from temporary diarrhea, or constipation.

SUMMARY

1. Chronic irritable colon is a very common functional disorder of the large intestine. It includes many cases previously diagnosed as chronic colitis, spastic constipation, nervous diarrhea and intestinal and gastric neuroses.

2. The most important etiological factors are an inherent irritability of Auerbach's plexus, the enema and cathartic habits, chronic colonic obstructions, improper dietary habits, debilitating diseases, chronic appendicitis, chronic cholecystitis and ureteral pathology.

3. Discovery and treatment of the etiological factors in the individual case is of paramount importance in therapy, but must be followed by dietary management.

4. Therapeutic failure indicates either that important underlying etiological factors have been overlooked, or that the patient has been unable or unwilling to cooperate sufficiently in the treatment.

The Treatment of Hourglass Stomach

By VICTOR PAUCHET,
Paris
(*Translation by Dr. L. T. de M. Sajous*)

This condition is characterized, as the term itself implies, by a mesogastric constriction which imparts to the stomach the shape of an hourglass. The organ is divided into two pouches, an upper or cardiac and a lower or pyloric, and these two pouches are connected by a canal or zone of constriction.

The hourglass condition may be due to one of the three following causes:

1. Spasm of the stomach muscle about an ulcer. An acute angled depression in the greater curvature is formed at a point exactly opposite the location of the ulcer on the lesser curvature.

2. Induration of the gastric parietes by a progressive fibrous ulcer. The ulcer is sometimes associated with a perigastritis and becomes surrounded with adhesions. The stomach walls, still soft and able to contract, immobilize the diseased portion of the organ.

3. Complete cicatrization of a healed ulcer. The segment of stomach intervening between the two pouches consists of a fibrous canal. The ulcer itself has gone on to recovery.

I have operated in forty-three cases of noncancerous mesogastric stenosis. In only eight instances was a narrowing due to healed ulcer, forming a fibrous ring between two stomach pouches, noted in the course of the operation. The other thirty-five cases revealed an ulcer still in process of running its course, and in about one half of these cases the ulcer was of the boring type, having destroyed the stomach wall and penetrated into neighboring structures—pancreas and abdominal wall.

The indication for operation necessarily varies in different cases. Personally, I always made use of the same procedure, viz., partial gastrectomy; the majority of surgeons, however, regard the indications as varying according to whether the ulcer present is active or healed.

FINDINGS UPON LAPAROTOMY

Ordinary cases.—A mesogastric constriction. This constriction is sometimes situated high up, the upper pouch being, accordingly, small; in other instances it is situated low down, in which event the lower pouch is of reduced size and the upper one very large.

The constriction exhibits the shape of a broken ring. It is excentric in location near the lesser curvature. On the peritoneal aspect there is noted a fibrous, white scar, hidden by perigastric adhesions.

In one half the cases there was found in the zone of constriction a boring ulcer penetrating into the pancreas, the liver, the abdominal wall, or sometimes in two or all of these directions simultaneously. The stomach as encountered in the operation does not always show the hourglass shape previously seen with the x ray. The true hourglass stomach is one the narrowed portion of which consists of a cicatricial canal at the site of a healed ulcer. As a matter of fact, the majority of bilocular fluoroscopic pictures relate to ulcers still in the progressive stage. Notably in the boring type of ulcer, a macula corresponding to the ulcer diverticulum is seen in the picture. This macula is located between the two dark areas representing the two pouches.

Other varieties.—Mesogastric stenosis present in conjunction with a duodenal stenosis; cancerous degeneration of a stenosing ulcer; gastrocolic fistula at the site of the narrowed, ulcerated segment; perigastric abscess about a stenosing ulcer.

TREATMENT

The treatment is always surgical.

Type I.—Hyperchlorhydria is absent; healing of the ulcer is complete; no trace of an ulceration remains, and the stomach walls are soft. In such a case the operator may rest satisfied with the performance of a gastrogastrostomy, a gastroplasty or an annular gastrectomy, followed by end to end gastrogastric suture.

Type II.—The ulcer is still in a state of activity, and the stomach walls are hard and thickened. The procedure required here is partial gastrectomy, i. e., removal of the pylorus, the antrum and the constricted portion, followed by gastroenterostomy (gastroduodenostomy or gastrojejunostomy).

This latter operation is indicated in most instances because of the fact that the ulcer is usually still progressive and that the only lastingly effective treatment of gastric ulcer is a wide gastrectomy.

The technic of the operation is as follows:

1. *Anesthesia.*—Regional, by infiltration of the parietes and block of the splanchnic nerves with one per cent. syncaine (procaine).

2. *Abdominal incision.*

3. *Abdominal exploration.*—The operator should ascertain whether the stomach is freely movable, the location of the constricted portion, whether an active ulcer is or is not present, and whether there are adhesions to be freed.

The operative technic necessarily varies in different cases. Following is the mode of procedure in a case of mesogastric stenosis of the intermediate type:

4. *Stripping of the greater curvature.*—The operator, laying hold of the pyloric antrum with his left hand, takes a gauze sponge with his right hand and rubs it over the insertion of the omentum in order to detach the latter from the greater curvature and pyloric pocket down to the duodenum. If the duodenum is broad, the upper pouch long, and the operator thinks he will be able to carry out a gastroduodenal anastomosis, he dispenses with the stripping of the lower border of the duodenum, which he preserves intact, since this structure is later to be united to the cardiac pouch. In the contrary event the stripping is continued over a portion of the duodenum, which is presently to be divided and closed as a blind end.

5. *Division of the duodenum.*—Two pairs of crushing forceps are applied on the duodenum immediately below the pylorus, and the gut divided with the knife between the two pairs of forceps.

6. *Division of the pyloric artery and gastrohepatic omentum.*—This is carried out with the knife in immediate contact with the lesser curvature.

7. *Liberation of the constricted segment.*—The stripping of the greater and lesser curvatures has first been carried out gradually to the point of constriction, whether the latter be associated with a progressive ulcer or a cicatricial stenosis.

The operator next proceeds to liberate the posterior surface of the stomach. Frequently the latter is the seat of a perforation and forms part of a boring ulcer which is penetrating into the pancreas or the liver. The knife is then passed in the thickness of the stomach wall immediately against the pancreas. It enters the gastric cavity. As there is risk of extravasation of the stomach contents, the operator passes an aspirator into the gastric cavity (cardiac aspect) and empties the latter. A pad is placed in the stomach. The liberation having been completed posteriorly, if the case is one of boring ulcer, the operator removes a bit of tissue from the margin of the pancreatic ulcer for a biopsy, in order to determine the ultimate prognosis of the excision. The ulcer may, indeed, be undergoing cancerous change.

8. *Division of the stomach.*—Previous to the division of the stomach it is generally of advantage to begin the anastomosis, introducing the posterior seroserous plane of sutures and joining the stomach either to the jejunum or the duodenum. This gastrointestinal suture has for its purpose to prevent retraction of the upper segment of the stomach. The duodenum having been brought in contact with the upper pouch and attached to it with a continuous seroserous suture, the operator resects the anterior wall of the gastric pouch above the constricted portion of the organ and the anastomosis is then continued in the three planes of suture.

9. *Gastrojejunal anastomosis.*—In case the gastric stump is too small, the stump of the duodenum should be closed with a double row of sutures or a purse string and the operation concluded with an implantation (Pólya) of the gastric stump in the jejunum. Where, on the other hand, a sufficiency of stomach and duodenal tissue is available, the operator should institute an end to end gastroduodenostomy (Péan or Billroth I operation).

In the event of a gastrojejunal anastomosis, if the jejunal loop is short, it is unnecessary to conclude the operation with a secondary button jejunojejunostomy; but if, on account of retraction of the stomach and the small size of the cardiac pouch, the operator carries out a long loop gastrojejunal anastomosis, a jejunojejunostomy with the Jaboulay button should be added.

Generally the anastomosis carried out is precolic. If, however, the mesocolon has been torn through during the operation, the loop should be passed through the opening in the mesocolon, constituting a retrocolic procedure.

If the operator is able to bring the opening in the mesocolon up to the gastric stump, he closes it by suturing it to the stomach. If, on the other hand, such a maneuver would require traction on the gastrojejunal suture line, he omits this step in the operation.

In my forty-three resections of the stomach for hourglass contraction there were three deaths and forty recoveries, or a mortality of about seven per cent. Many cases call for difficult operative procedures. The mortality is, however, increasingly tending downward. The mortality in my cases of resection of the stomach for ulcer now ranges from about two to three per cent.

Study of the late results of this operation warrants the assertion that, of all the operations employed, partial gastrectomy with gastrojejunal or gastroduodenal implantation is the procedure giving by far the best results. *I have not observed a single therapeutic failure.* There is no form of postoperative disturbance among the after results.

It may be stated as an axiom that the more widely the operator removes the stomach walls for gastric ulcer, the better are the remote operative results.

Diverticula of the Stomach*

SAMUEL WEISS, M.D., F.A.C.P.,
New York

Diverticula of the stomach is by no means a common occurrence; if present, it may easily be overlooked by the novice or even by others more experienced unless they are thoroughly conversant with the normal variations of the human stomach as viewed under the fluoroscope or upon the film. The excavation into adjacent tissue sometimes produced by perforating gastric ulcer is not really a diverticulum, though often thus called. Pathologists customarily divide diverticula into the true and false. In the former the diverticular sac contains all the coats of the viscus mucosa, muscle and serosa; in the false type one or more layers are missing, most often the muscular, in which case the condition has been described as hernia mucosa.

I will report two cases of diverticula, both having been operated upon and the diagnosis confirmed. These patients have been under the care of competent physicians and have been dieting and taking drugs without benefit.

Case I.—H. J., aged forty-nine, married, a furrier, weight one hundred and thirty-four and a half pounds. His family history was negative. His past history showed that for thirty-two years he had had

*Presented before the Clinical Society of the Jewish Memorial Hospital, January 6, 1925.

Fig. 1.—Prone position Fig. 2.—Modified oblique Fig. 3.—After six hours

a burning sensation coming on one or two hours after meals. At times he was relieved for days or weeks. His present complaint was loss of weight, with cramps in epigastrium radiating to abdomen and back (left). His appetite was poor, he was nauseated and belched a great deal; no actual vomiting. Bowels were constipated. Food gave temporary relief, but after several hours, depending upon the quantity and quality of food, the pain became more severe. No relief was obtained from alkalies or belladonna.

Physical examination.—Patient seemed to be suffering a great deal. His hand was on the epigastrium pressing towards the spine which eased the pain somewhat. Pulse, 72; temperature, 98.4; respirations, 28; blood pressure, systolic 110, diastolic 85. Heart and lungs were normal. There was tenderness in the epigastric region and left hypochondrium, and also marked tenderness to the left of the umbilicus. Change of position: patient lying on the right side seemed to have increased tenderness in the epigastric region and tenderness was also elicited in the right hypochondrium. The latter was not present in the prone position. Deep pressure in the epigastrium seemed to relieve the pain but was followed by excruciating pain afterwards. A tentative diagnosis of gastre ulcer was made.

Laboratory examination.—Urine and stool, negative. Test breakfast: Free hydrochloric acid, 25; total acid, 42; combined, 17. Microscopic findings were negative. Blood: hemoglobin, 65; white blood cells, 5600; polymorphonuclears, 55 per cent.; mononuclears, 3 per cent.; transitionals, 5 per cent.; lymphocytes, 37 per cent.

Röntgen examination.—Chest and heart, negative; eosphagus, negative. Stomach, observation under the fluoroscope while drinking a barium buttermilk mixture showed a moderate sized stomach, poor in tone, and absence of peristalsis. Further observation revealed a pouch two or three inches below the cardia with a smaller pouch protruding from the larger one. On palpation part of the barium was pressed back into the stomach and the patient complained of pain. On the lesser curvature near the pars media there was a large niche also tender to touch. Patient was given two medium boiled eggs, some bread and butter and a glass of water. Reexamination an hour later confirmed the diagnosis of ulcer on the lesser curvature and a large diverticulum. Six hour examination showed a partly emptied stomach with barium in the diverticulum and niche. Patient complained of severe cramps in the upper abdomen and radiating to the back. These pains came on about two and a half hours after the ingestion of barium buttermilk and eggs. The twenty-four hour examination showed a small gastric residue and the diverticulum was still filled with barium. No further examination was made. The patient was referred to the surgeon for operation.

Report of the surgeon.—The abdomen was opened and the stomach exposed and examined. About two and one half inches below the cardia and densely surrounded by adhesions, was a small mass the size of a hazel nut, with a tube attached to the lesser curvature of the stomach. After carefully dissecting it from the surrounding adhesions the stomach was incised and a probe passed into this tube and through it to the small sac attached to it. The entire thing was excised and the incision in the stomach closed. The patient's condition did not permit any further manipulation and the large ulcer near the pars media was permitted to remain.

The patient made an uneventful recovery and was discharged from the hospital after three weeks. At home the patient was put on the Sippy diet for ulcer and within three months no trace of the niche remained. The lesser curvature, with the exception of a slight indentation about two and a half inches below the cardia, was smooth and the emptying time of his stomach and peristalsis were normal.

The patient has been under observation from time to time, his diet is carefully supervised and his mode of life regulated. His present weight is 165 pounds.

Report of the pathologist.—Examination of the specimen removed from H. J. shows a narrow tortuous tube ending in a small pouch about the size of a hazel nut. On incision it was found full of barium and some stringy mucus with food particles adhering to it. Microscopic examination of frozen sections reveals the presence of all the coats of the stomach.

Case II.—H. L., aged forty-nine, business man, weight 124 pounds. Family history was negative. Past history was also negative except for stomach trouble for the past nine years.

Present complaint.—The patient complained of being attacked with abdominal distention and pressure in the epigastrium after eating certain foods. These attacks occurred seldom, but when they did they were quite severe. The patient did not vomit, there was no burning, the appetite was fair, bowels were irregular.

Physical examination.—Pulse and temperature normal. Heart and chest negative. Blood pressure 100-85. Marked tenderness and some rigidity to right of the median lie midway between the ninth cartilage and the umbilicus. Position did not change the location of the tenderness. Clinical diagnosis, cholecystitis and possibly cholelithiasis.

Laboratory findings.—Urine and stool negative. Test breakfast: Free hydrochloric acid, 46 per cent.; total acid, 61 per cent.; microscopic findings, negative. Blood: hemoglobin, 90 per cent.; white blood cells, 8400; polymorphonuclears, 65 per cent.; mononuclears, 3 per cent.; transitionals, 5 per cent.; lymphocytes, 27 per cent.

Röntgen examination.—Heart and chest, negative; esophagus, negative; stomach, moderate ptosis otherwise negative; duodenum, cerrated, adherent to gallbladder and on manipulation a marked projection was noticed which was quite tender to touch. Opposite to this a constant deformity or incisure was present. A diagnosis of duodenal ulcer with periduodenal adhesions was entertained, and in view of the findings and the chronicity of the case the patient decided to be operated upon.

Report of the operation.—After the usual preparation the abdomen was opened, the gallbladder was found surrounded by dense adhesions, also a small healed ulcer of the duodenum was found. Further examination of the duodenum revealed a small pouch which was excised and on examination proved to be a diverticulum of the duodenum. The pathologist reported a true diverticulum.

The patient made an uneventful recovery and is under observation at the present writing. Röntgen examination shows a normally functioning stomach and duodenum.

777 Madison Avenue.

How to Make a Snapshot Diagnosis of Hemorrhoids

J. F. MONTAGUE, M.D.,
New York

The term snapshot diagnosis arose some years ago from the seeming ability of a clever diagnostician to arrive at a formed diagnosis of whatever case presented itself to his notice with about the same rapidity that one may take a snapshot picture with a camera. Since that time, those of us who aim to be considered clever attempt to emulate the aforementioned worthy and make our diagnoses instantaneously. The following paragraphs are a sure guidance for the attainment of such skill.

A patient presents himself at your office and complains of pain upon defecation. Plainly the snapshot diagnosis is hemorrhoids! Careful proctoscopic examination, however, shows the presence of an anal fissure but an otherwise normal rectum and anus.

Another patient complains of a protrusion from the rectum upon defecation. What could be simpler than the snapshot diagnosis—hemorrhoids! Careful proctoscopic examination reveals the presence of a large prolapse of the rectum which protrudes to the extent of three inches from the anus following defecation and which may be manually replaced.

Yet another patient complains of bleeding from the rectum and soreness upon defecation with intermittent soreness at other times. Swift and sure comes the snapshot diagnosis—hemorrhoids! Careful proctoscopic examination, however, leads one to the conclusion that the cause of the patient's soreness and bleeding lies in a chronic ulcer of the rectum.

The next patient tells you he has piles—"itching piles." So nothing could be more certain than the snapshot diagnosis—hemorrhoids! Proctoscopic examination, however, to the contrary, shows the absence of hemorrhoids and the presence of condylomata about the anus.

Finally, there comes a patient in whom we have a history of persistent bleeding and some pain upon defecation. Nothing could be more definite than the diagnosis of hemorrhoids. Unfortunately, however, thorough proctoscopic examination discloses the presence of a large ulcerating mass infiltrating the rectal wall and a biopsy of this shows it to be an adenocarcinoma of the rectum.

I fear that in the instances mentioned above I have spoiled a good story by sticking in the facts, but facts are troublesome things to deal with if repressed, for, like murder, they will "out," sometimes to somebody's embarrassment. We would not expect a camera to take a picture without allowing it the privilege of at least one look, so we cannot logically expect to arrive at a conclusion as to the nature of rectal ailments without being accorded the privilege of a look which, in this instance, should consist of a careful proctosigmoidoscopic examination.

You may be assured that there is but little exaggeration in the foregoing. It is, I am sorry to say, true to life. The causes responsible for such a situation are partly the false modesty of patients in respect to rectal ailments and partly the indulgence of those physicians who permit themselves to arrive at a diagnosis of rectal ailments without making a rectal examination. It might be of service to remember that *not all rectal pains are due to piles nor is all rectal hemorrhage indicative of hemorrhoids.*

540 Park Avenue.

Historical Medicine

Comparison Between the Third and Fourth Eras of Surgery*

ROBERT T. MORRIS, M.D., F.A.C.S.
New York.

After centuries of surgery belonging to the first or heroic era in which surgeons did not have competent knowledge of anatomy or of wound treatment there came the second era. Andreas Vesalius may properly be called the father of the second era, although he was subjected to so much persecution that we had to wait for John Hunter before this era was in full swing. It included the idea of the surgeon possessing high degree of knowledge of anatomy and developing manual skill in the performance of surgical work.

Such progress was made that Napoleon's surgeon, Baron Larrey, said that surgery had reached its limitations. Surgeons in the future could look forward to nothing more excepting to acquire knowledge of what was already known and to the perfecting of their personal technic. Since the time when surgery had "reached its limitations" two great eras, each with explosive new features, have appeared and we cannot even hazard a guess as to what the fifth era will be like unless we imagine that it may relate to preventive surgery. By that I mean that we may learn to prevent the development of malignant neoplasms and we may inhibit toxic processes which lead to the formation of gall stones, stones in the urinary system and the development of gastric ulcer for example.

A fifth or preventive era of surgery may perhaps even go so far as to include eugenic control which will avert the deformities belonging to arrested development. Incidentally, it may even extend into traffic regulations in such a way that we shall have fewer automobile accidents.

Right now we are concerned chiefly with the third and fourth eras of surgery. The third era emerged when Lister made surgical application of Pasteur's work with microbes. The principles of the third era included the idea of destroying microbes and of disposing of their poisonous byproducts, but it did not take into account the protective resources of the patient himself. That idea was left for development in the fourth era of surgery, in the course of enlargement of our art. During the third era with the patient himself left out of consideration, the greatest and most rapid advance in this whole history of surgery, up to that time, was made.

Vices which developed were incidental to the virtues. Under the protection of antisepsis and of asepsis, operators who had no right to ever touch a knife engaged in surgical work which required the highest type of technical work on the part of experts. The mistaken idea of glory seemed to go with operative work so that in many localities men who had in no way given themselves opportunities for training as surgeons felt that they must operate in order to retain their dignity in a community. This would not have been possible during the second era of surgery because an extensive knowledge of anatomy would have been essential and in the second place so many patients would have promptly died that the occasional operator would have met promptly with public disapproval. So many of his patients now make some sort of recovery, no matter what is done to them, that it led the late Dr. Maurice H. Richardson to exclaim, "What a pity it is that so many patients recover from the kind of surgical work that is done for them today!"

Another vice belonging to the third era of surgery in which the patient himself was left out of the running consisted in deliberate long continued operative work aided by new confidence in anesthesia. Crile has shown us that destructive impulses are constantly being sent into the centres of consciousness of the anesthetized patient.

Operations of a sort which were sometimes performed in less than a minute during the anatomical era of surgery were frequently drawn out into an hour or more of work during the third era. This vice of deliberate and unduly prolonged operation was finally recognized and classified in its proper position.

Another vice belonging to the third era resulted in perhaps hundreds of thousands of deaths. It was the idea that in abdominal surgery we must remove all pus or other infective material. We had forgotten that patients with appendicitis with abscess, with ruptured gallbladder or even with typhoid perforation, sometimes recovered without operation. If all of us were to know what we have forgotten we would make more rapid progress than we do at the present time. Having forgotten that patients with pus and infective material in the peritoneal cavity sometimes recovered while in the hands of old time medical practitioners, we proceeded to try more or less violent measures when dealing with peritoneal microbes and their products. We forgot that bacteria were at work in the tissues rather than in the fluid byproducts. Washing and wiping of intraabdominal viscera was not only extremely injurious and shocking, but it was unnecessary.

The employment of gauze packing and of extensive drainage device belonged among the vices of the third era of surgery. Long incisions which "exposed all of the pathology" exposed more than that when they extended to the patient's last degree of resistance. Dr. Thomas L. Bennett, the anesthetist who has had experience with very many surgeons, once said: "The best surgeon is the one who acts all the while as though he were afraid of waking the patient up." Much of the violent surgery belonging to the third era had a tendency to wake the patient up and to find himself among

*Read before the Buffalo Academy of Medicine, March 4, 1925.

celestial surroundings. At the height of the third era of surgery in New York, the death rate after appendicitis operations at the J. Hood Wright Hospital, where many emergency cases were received, was thirty-one per cent. Dr. L. W. Hotchkiss, viewing with alarm the death rate according to accepted principles of the third era in this particular field of its application, suddenly turned directly about and applied the principles of the fourth era or physiological era in surgery. As soon as he had done this he had a run of seventy-six consecutive appendicitis operations without a death in the same sort of complicated appendicitis work which had previously given a death rate of thirty-one per cent.

The fourth, or physiological, era of surgery emerged when Metchnikoff and Wright showed us the protective forces of the individual. They told us about phagocytosis, opsonins and gave us an explanation for the recovery of patients from severe infection in the days before we knew anything about microbes. They showed us how patients in ignorance of microbes got well under the care of physicians who were also ignorant on that subject.

When Metchnikoff and Wright reminded us of what we had forgotten in this connection and in addition gave sound instruction about the way in which patients brought their own internal resources to bear we then had the first sunlight which allowed fourth era principles to grow. The fourth era surgeon does not wipe away pus and other discharges from a wound in such a way as to injure the new cell formation beneath. He is not obsessed by any gross idea of cleanliness. He does not try to get all infective material out of the peritoneal cavity, knowing as he does that it would be impossible to do so and furthermore that his attempts at cleansing the peritoneal cavity would so shock the patient that infection remaining might flare up in an uncontrollable conflagration. A fourth era surgeon does not use unnecessarily long incisions or prolong an operation for the purposes of any pretty detail in technic. He completes his work in the most workmanlike manner possible if it does not interfere with the vital processes of the patient. In that latter case he allows his technic to suffer and saves a life by preference. Principles of the fourth era of surgery may be stated briefly by saying that they give the patient home rule. In other words, the patient is turned over to himself in the speediest manner possible and with the least degree of surgery which will suffice for turning the tide in battle between microbe and patient.

114 East Fifty-fourth Street.

William Crawford Gorgas

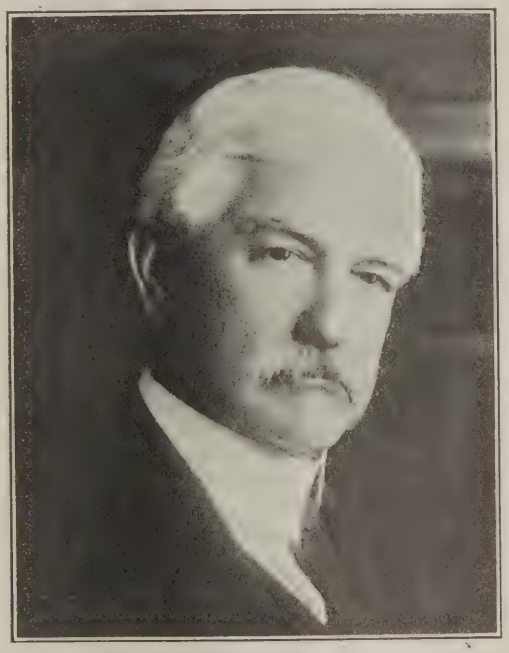
The recent announcement of the definite plans of the Gorgas Memorial Foundation, established to be a living monument to the name of the American physician who will always be remembered in the history of medical science as the man who put an end to the plague of yellow fever, makes timely a sketch of his early life, less well known than his latter years. Within the last few months an interesting biography of Gorgas, written by his wife, Marie D. Gorgas, and his friend, Burton J. Hendrick, has been issued by Lea & Febiger, of Philadelphia, and it is for the most part from this book that the facts given here are gathered.

The name Gorgas suggests a Spanish origin, but if this was true, all account of it has been lost, for when the first Gorgas came to this country in 1680 the family was unmistakably Dutch. They settled in Pennsylvania and intermarried with many of the leading families of that state. The doctor's great grandmother was named Psyche Rittenhouse, and his grandfather married "the beautiful Sophia Atkinson." Their son, Josiah, was the father of William, who was the first child. His mother was a lady of unusual intelligence and charm, Miss Amelia Gayle, daughter of the Governor of Alabama.

William Crawford Gorgas was born on October 3, 1854, in the old Gayle place near Toulminville, near Mobile. His father and mother were both very prominent in social and political circles, and the family spent much time at the capital of Alabama, and at Washington, when Webster, Clay and Calhoun were the leaders of the Senate. Later Josiah Gorgas was assigned by the Government to the command of the arsenal at Augusta, Me., and the family moved thither. It is here that "Willie" appears as a character in the journal that his father kept and is recorded as "very bright, quite grave, and tolerably mischievous and troublesome." He loved swimming, boating and hunting, but the greatest delight of his boyhood was his donkey. In the South he had a little negro boy as his constant companion and playmate, as was the case with most little Southern boys, with whom he had many battles. "At school," writes his wife, "Willie had mighty combats. On one occasion he stood alone against his whole class, the weapons being slates; his sister, Minnie, ably seconded him, piling up ammunition which the boy, sometimes with excellent judgment, hurled at the advancing foe." A military career had always fascinated him. His mother, a very religious woman, was much disappointed when she found out that the reason her son spent so many hours prone on the floor, immersed in the sacred pages of the Bible, was chiefly to revel in the descriptions of the battles of the Israelites.

When the Civil War broke out, there were family difficulties, for Josiah Gorgas was a Northern man and an officer in the Federal army, but his marriage

nto a Southern family and his many years' sojourn n the South had virtually transformed him into a Southerner and a Democrat, so that he accepted all the principles of the South, including slavery. So he decided to ally himself to the cause of the Confederacy and was at once commissioned a brigadier and made Chief of Ordnance in the Confederate forces. William was seven when the conflict began and throughout the succeeding four years constantly haunted the Richmond arsenal, where his father was stationed. When in the end the Union troops swarmed into Richmond after the retreating Confederates, his father as part of the army was ordered to leave. Summoning William, now eleven, he made him realize that the safety of his mother and sisters rested in his hands, and that, since the arsenal, which was near the Gorgas home, was to be blown up, he must lead the others as soon as a certain house caught fire to an uncle's home. The description of this flight is both pathetic and amusing: "He enjoined him especially not to forget the family cow. Soon a considerable part of the city including the arsenal was ablaze, and the sight of the exulting Federal troops coming over the hill added to the excitement. The Gorgas family abandoned their home and started up the street to their appointed refuge; William led the procession, with his invaluable cow tied to a halter; his four little sisters followed, clinging to the skirts of their mother, who held the baby in her arms. The town was full of disorder; a mob of both blacks and whites, stimulated by liquor, was engaging in wholesale plunder, and the fire of a hundred buildings illuminated a scene of riot and horror. Suddenly a terrific explosion took place; the air was full of bursting projectiles; the arsenal had caught fire. Every member of the Gorgas family except one bore the shock with coolness; the one that gave evidence of excitement was the cow, which frantically cavorted right and left, pulling its youthful custodian in all directions. Willie, however, persistently held the rope; amid crackling flame and exploding shells at a corner of two streets a fragment of shell hit the excited animal; she gave one spring into the air, hurling William head first against a cobblestone, and so dazing him that, when he regained his composure, the cow had completely vanished from the history of the Gorgas family. Willie keenly felt his disgrace; he had not fulfilled his father's injunction and he refused to be comforted. 'It's not so bad, Willie,' said his mother. 'Just think, that shell might have hit your baby brother instead of the cow.' 'I thought at the time,' Gorgas said afterward, recalling the incident, 'that women had a greatly exaggerated idea of the value of babies.'"



WILLIAM C. GORGAS

The war reduced the family to dire need, and relatives in Baltimore cared for them until General Gorgas received the appointment of president of Sewanee University, a post which he occupied for ten years. William pursued his education at Sewanee, manifesting while there the two outstanding traits of his character, a deep religious fervor and a zest for military life. Sometimes before going into a baseball game, a sport in which he was very proficient, he would offer up a prayer for victory. His father discouraged him continuously from taking up a military career, but finally gave way and consented to try to get his son an appointment at West Point, but failed in his attempts for various reasons. "Looking back now his West Point failure," writes his biographer, "seems almost like a dispensation, for certainly Gorgas as a cavalry or an infantry officer could hardly have exercised the influence in the world that fate had marked out for him. There was one way, and only one way, in which Gorgas now could get into the army; that was by way of the medical corps. Yet the subject on which he had shown no interest as a young man was medicine. . . . But medicine at this crisis had one advantage that compensated for the mere anatomy, physiology and pathology with which it was encumbered; it was an indispensable part of every military establishment. In order to get near the powder and shell Gorgas was willing to endure this otherwise valueless lumber. Again his father was aghast at the suggestion. Medicine was a great profession—yes, that would be splendid; but an army doctor! The general had become rather familiar with the type in his own military experiences, and the prospect of his son in such a position did not flatter his paternal pride. Yet, as usual, there was nothing to do in face of the boy's quiet insistence. He would be a military man, even though in no loftier light than that of a military doctor. The autumn of 1876 therefore found Gorgas enrolled in the Bellevue Medical College in New York City, living on the modest stipend which his father could send him. . . . The profession which he would never have chosen except as a stepping stone to the army, presently enthralled him. The dissecting room and the operating theatre now began to draw out his finest mental qualities. . . ." He made an excellent record as a student, part of his last year serving on the staff of the mental hospital at Blackwell's Island. He received his degree in June, 1879. After a brief interneship at Bellevue Hospital in 1880 he entered the medical department of the United States Army, and spent the next two

decades of his life in the every day matter of fact career of an army doctor.

It was during the Spanish-American war that his real career began, with his appointment in 1898 as chief sanitary officer of Havana. From that time on Gorgas's story is too well known to need repetition here. The marvelous part of it all is that he was able to succeed and to attain such splendid results in his mosquito extermination work in the face of almost no support, until Roosevelt realized what he was doing, and with very bitter opposition in many quarters from which aid might have been expected. It is of some consolation that honors were heaped on him in the end, and that the name of William Gorgas became known throughout the civilized world.

A Biographical History of Physical Diagnosis.—William Shainline Middleton writes (*Annals of Medical History,* December, 1924) that "tradition traces the beginnings of physical diagnosis dimly back through the centuries before Christ to the empiricists of Egypt and India. However hazy may be this evidence, Aryan practitioners made use of palpation, percussion and auscultation as early as the second century A.D., according to Charaka. Antedating this period by more than five centuries, however, physical diagnosis may be said to take its inception in the Golden Age of Greece, and its founder in the person of the Father of Medicine, Hippocrates." His patent honesty and detailed accuracy have made his contributions immortal. The Book of Prognostics, Book of the Epidemics, and the Aphorisms are believed to have been written by him and are a bountiful storehouse of information. The first reference to clubbed fingers is found in Hippocrates, probably the first description of the Cheyne-Stokes type of breathing, convulsions of the contralateral extremities subsequent to head injuries were remarked, globus hystericus was accurately described, as was also coma vigil, the connection between fistula in ano and phthisis, the form of body peculiar to phthisical complaints, and aphonia was recognized as an accompaniment to tuberculosis. Hippocrates's contributions to physical diagnosis were not limited to inspection. He practised palpation of the abdomen, and immediate auscultation in a rudimentary fashion. He unquestionably recognized râles. Hippocrates's art and philosophy in the practise of medicine are shown in the following quotation: "The physician must be able to tell the antecedents, know the present, and foretell the future —must mediate these things, and have two special objects in view with regard to diseases, namely, to do good or to do no harm. The art consists in three things—the disease, the patient, and the physician. The physician is the servant, and the patient must combat the disease along with the physician."

The passing of Hippocrates in 370 B.C. initiated a seemingly interminable period of inactivity in the development of physical diagnosis. Not until the time of Paracelsus, 1493-1541, was the tide of theorism in diagnosis turned back for the safer ground of observation. Prompted by his devotion to Hippocrates, he, on assuming the chair of medicine at Basel, publicly burned the works of Galen and Avicenna. After Paracelsus, Thomas Sydenham (1624-89) stands out as the reviver of Hippocratic and as one of the greatest bedside physicians of all times. Practical clinical contact and accurate portrayal of disease mark his contributions.

Herophilus of Alexandria (335-280 B.C.) was the first physician to study the pulse. Galen established a system of medicine on the minutiæ of pulse variations. Accurate timing of the pulse was instituted by Galileo Galilei (1564-1642), although Sanctorius is incorrectly credited with this contribution to medical science. Galileo's instrument was the "pulsilogon." Morgagni recorded the first example of heart block, Sir John Floyer in 1707 dedicated "the physician's pulse watch" to Queen Anne, but subsequently the pulse was disregarded for two hundred years until Louis and the Dublin School reinstated routine pulse determination. Galileo invented also the first rude thermometer, but Sanctorius (1561-1636) devised an improved instrument for recording body temperature by the mouth; to him belongs the credit for the first application of thermometry to medicine. Improvements were made by George Martine, Carl Wunderlich and John Hunter, but it was not until 1868 that Sir Clifford Allbutt developed the clinical thermometer to its present form.

With the exception of these two contributions pulse recording and thermometry, physical diagnosis was peculiarly sterile until the time of Leopold Auenbrugger (1722-1809), who added percussion. This method was developed by Jean Nicholas Corvisart. His writings are among the first clinical records of physical findings specifically corroborated by necropsy. He differentiated active from passive aneurysm of the heart, and obviously practised palpation and auscultation in his cardiac studies. The brilliancy of his diagnostic powers is illustrated in a story told of how one day he passed a portrait and remarked that the subject was a cardiac case. Inquiry proved that this was indeed true. "Truly a giant among clinicians, and an able diagnostician and teacher, Corvisart deserves to be ranked as the father of modern objective diagnosis." He died of heart disease. His mantle fell upon Laennec, the inventor of the stethoscope, who established the fruitful field of mediate auscultation. He originated the term cirrhosis of the liver. The work of Corvisart and Laennec was continued by Louis, Piorry, Chomel, Andral and Reynaud. The application of the numerical method to the practice of medicine was one of Louis's great contributions. He was the first clinician to count the pulse routinely, but his greatest service was the spreading of the gospel of exact clinical methods. Piorry's contribution of note was the plexímeter.

Robert Graves (1896-1853), an Irishman, introduced into clinical teaching examination and real care of patients by the students; he first observed the pinpoint pupil and described exophthalmic goitre. William Stokes (1804-78) took Laennec as his guiding star and set himself the task of improving the status of mediate auscultation. He was the first to use the finger as a plexímeter in percussion, and to note the inconstancy of fluid movement in the thorax. The Cheyne-Stokes respiration is rightfully named after him, but the Stokes-Adams syndrome right

fully belongs to Morgagni. Two other members of the Dublin School—Sir Dominic Corrigan and John Cheyne—are famous in diagnosis, the former through his fine monograph on *The Permanent Patency of the Mouth of the Aorta or Inadequacy of the Aortic Valves;* and the latter for Cheyne-Stokes respiration.

The work of the more modern and hence better known physicians discussed in the remainder of Middleton's valuable paper may be suggested by a list of the names included: Sir Richard Bright, famed for his knowledge of nephritis; Sir Thomas Addison, one of the greatest of the teachers of medicine; Johann Lucas Schönlein, who introduced bedside teaching into Germany and was the first clinician to use the microscope routinely in diagnosis; Joseph Skoda, who was partially successful in his attempt to replace the inexact terminology of the French school by a system based on quasiphysical laws; and the Americans, James Jackson, Jr., William Wood Gerhard, and Austin Flint, Sr., (1812-1886) who was ranked as the ablest clinician of his day in America. The writer includes exceedingly interesting biographic sketches of the men discussed. The article is concluded with a reprint of the famous *Stethoscope Song,* by Oliver Wendell Holmes.

The Medicohistorical Movement: Italian Societies of Medical History.—Jean Avalon writes (*Æsculape,* February, 1925) that Dr. Chiapparelli states, in his study of the practice of medicine during the Middle Ages, that for a long time only the monks practised this art. All the monasteries and abbeys had a room where they received pilgrims and the sick. The monks delegated to care for the poor were considered by the faithful as doctors of both soul and body, for the malady was a divine chastisement to be treated with prayers and remedies. The monks probably encouraged these superstitions, for the pilgrimages to their monasteries were a source of considerable income. They also distributed talismans, phylacteries, and other tokens to which a protective virtue was attached. The clergy preached against charlatans, denivers, sorcerers, but upheld superstitious practices, among them the wearing of a string blessed by a priest around the neck of both men and animals. In the hospices and convents the practices were handed down from generation to generation, and in some such way of giving charitable treatment the medical school of Mount Cassin had its origin and played its part in establishing in the tenth century the school of Salerno.

A change came with the decrease of faith and Christian charity, and treatment was given in the hope of material recompense, until the evil became so prevalent that the Council of Rheims in 1131 forbade to the clergy the study of medicine, and subsequent Councils imposed heavy penalties on giving charitable treatment. These measures resulted in the establishment of lay practitioners, some real physicians, others charlatans.

Up to the end of the thirteenth century, doctors prepared their own medicaments. When they had no time, they relegated the job to a son or an apprentice, called a *ministrum medicorum.* The doctor's title was *megister.* This practice of preparing the medicines made it necessary for the physician to have a garden of medicinal plants. There were also in the Middle Ages women *medicæ.* They practised principally at Salerno, but seem to have confined themselves to the treatment of pregnant women and of children.

Sanctorius Santorio, born at Capodistria in 1561, educated in medicine at Padua, practised in Venice. He was in a way the founder of physiology and metabolism. He was the first physician to use the thermometer in illness. His instrument was of the most primitive nature, consisting of a ball of glass filled with air, welded to a tube open at one end which was plunged into a tank of colored liquid. He was the inventor also of the *pulsilogium.* But his greatest fame rests on his balance for weighing transpiration. His book, *Ars de Statica Medicina,* was violently attacked; however, it went through no less than twenty editions between 1614 and 1736.

The writer closes his paper with a brief abstract of an article on the Medicine of India by Vallauri, and quotations from a book review by Dr. Carbonelli of an ancient book on the plague, translated from many languages. One curious feature of the book is a short list of books which the reader is advised to read in the times of epidemics to *soulager l'esprit.* One of the list is *Il Libro delle cento novelle,* which is none other than the *Decameron* of Boccaccio; another is Ovid's *Art of Love.*

Recent Progress of Treatment by Sunlight.—In 1903, Dr. A. Rollier opened at Leysin, in the Alpes Vaudoises, the first clinic for the treatment of socalled surgical tuberculosis by sunlight, Dr. Saleeby tells us in his book, *Sunlight and Health.* In 1910, Rollier applied his idea to prevention by the establishment of his "school in the sun" at Cergnat, near Leysin. In 1914 appeared his book, *La Cure de Soleil,* which was almost forgotten in the war.

In Great Britain, Rollier's methods were taken up and followed by Sir Henry Gauvain at the Treloar Hospital at Alton and Hayling Island, where very simple sheds and solaria achieve the most successful results. In a few other places, among them the Queen Mary's Hospital for Children at Carshalton, at Leasowe near Liverpool, at the Heritage Crafts School at Chailey in Sussex, and at Perrysburg near Buffalo, New York, the sun cure is employed.

Since, however, the bases were lacking for a successful empirical practice, conducted by various clinicians under widely varying conditions and in ignorance, for the most part, of each other's methods, and since no rational statement of the value of heliotherapy seemed available, Dr. Saleeby proposed that a properly conducted scientific inquiry be made into the action of sunlight upon the body in health and disease. This plan was acted upon by the Medical Research Council early in 1922, and appointed a special committee under the chairmanship of Sir William Bayliss to make such an inquiry.

The writer goes on to tell us of successful results of the treatment in the Light Department of the London Hospital, and of his observation of the work in various American laboratories, especially at Columbia University under Dr. Alfred Hess and his colleagues. He believes that the death rate in New York City from pulmonary tuberculosis fell fifty per cent. in the period 1905-9 largely because of the enactment of a sanitary regulation against smoke.

Editorial Articles

ABERNETHY AND THE INTESTINAL TRACT

Evidence is being gathered continually of the clinical acumen and foresight of the practitioners of bygone days. Conditions which are now discussed almost as if little or nothing was known about them formerly, the doctors of one hundred years and more ago had observed closely, in a general way had diagnosed accurately, and had treated effectively.

John Abernethy was one of these pioneers. He was one of the first to recognize the menace of chronic constipation and his methods of treatment were in keeping with the practice of the present day. Mr. Percy Dunn, of London, has an illuminating article on Abernethy in the *Franco-British Medical Review,* March, 1925. In Abernethy's book which he termed *My Book* he wrote at length of the effects of neglected constipation. With regard to constipation he said: "Imperfect digestion must influence the quality of the blood, and all parts of the body may be affected from this source."

Although intestinal toxemia was unknown then at least, not known in those terms of course, he referred to that condition. He also quotes in *My Book* the independent testimony of a French alienist in 1806 in support of his views. This alienist anticipating the modern teaching on the subject, pointed out the determining influence of neglected constipation in the causation of mental disease and insisted on an evacuant treatment as yielding successful results in his hands, affirming also that many other diseases were curable by the same treatment, where disorders of the digestive system were present.

Abernethy pointed out that diseased vascular action, due to continued disorders of the gastrointestinal tract, led to alterations of structure in the irritated parts, which is only another mode of saying that intestinal toxemia causes or paves the way for arteriosclerosis, chronic articular rheumatism, rheumatoid arthritis, and other affections of a like nature.

Abernethy described the postmortem signs of a mucous colitis and showed that these signs were the direct sequelæ of neglected constipation. Further, his definition of chronic constipation agrees with that of intestinal stasis of the present day. He held that a daily action of the bowels was no proof that a person did not suffer from constipation and he also pointed out that the large intestine was more greatly in fault than the small. Abernethy seemed to have observed no mechanical means for delaying the passage of the feces, Sir Arbuthnot Lane was the first to draw attention to kinks. He relied upon calomel to relieve chronic constipation, which he gave in small doses to stimulate the secretion of bile. He was strongly averse to the free use of strong purgatives. He prescribed small doses of calomel about three times a week, combined with a daily dose of some vegetable laxative, such as tincture of rhubarb or infusion of senna.

Abernethy took the stand that strong stimuli will increase the unhealthy conditions of weak and irritable parts. It is possible, too, that calomel acted to some extent as an intestinal disinfectant, although from this point of view its employment has been superseded in recent years by a more reliable preparation by far.

Abernethy expressed views with regard to the origin of cancer practically identical with those held by some authorities at the present time. In *My Book* he says: "Even in cancer, disorder of the digestive organs appears to be antecedent to the local disease, and aggravated by its existence." He adds: "But whether this disorder be the effect or the cause of the constitutional diathesis cannot, I think, be at present determined." It may be mentioned that Abernethy believed in diet as a means for combating disease successfully and especially in constipation, and he was strongly opposed to the gross habits of eating and drinking which were prevalent in his day. Enough, however, has been said to show that Abernethy was a pioneer, and that the clinical experience which the doctors of the old school possessed led them within limits to accurate diagnosis and that while their methods of treatment were not scientific from the modern viewpoint, they were effective. Experience and common sense were their guides.

THE PHYSICIAN AND THE PUBLIC HEALTH

The practice of medicine has changed in the past sixty years and is still undergoing evolution or rather development in the right direction it is to be hoped. Only a few years ago the practice of medicine hinged virtually on curative and remedial treatment and now it is veering towards prevention and preventive treatment. Attention is directed to these changing conditions in the *Boston Medical and Surgical Journal,* December 4, 1924, in a forcible article contributed by Professor Hans Zinsser, being the ether day address delivered on October 6, 1924, at the Massachusetts General Hospital. It is pointed out that it is in the activities of preventive medicine that the

medical profession and the public have begun most thoroughly to understand each other. It is not only that the impossibility of accomplishing lasting results without public confidence has been recognized, but that the intelligent public is making amazing progress in sound comprehension of the principles underlying protective measures, and has learned that these activities are not exclusively the responsibilities of medicine. The main reason for this attitude said Professor Zinsser is that it has long been apparent that in problems in which the medical aspects are intimately interlaced with economic, sociological, educational, industrial and occasionally even religious considerations, the public itself must eventually take the decision, the medical profession merely setting the compass. While preventive medicine has made and is making so great advances in all civilized countries, indeed the stage of civilization attained by any country may be gauged with a fair degree of accuracy by its public health statistics, almost wholly through the cooperation of the public. This state of affairs does not relieve the medical profession of responsibility.

Although the cooperation of all classes of the community is indispensable for success, yet the foundation and underlying principles upon which the structure rests are medical and in addition the central body of workers who give direction, define objectives and furnish information to the specialists must be medically trained. And again, the responsibilities of individual practitioners are enchanced rather than diminished by these developments. For, as the writer points out, the physician represents the first line of defense and therefore seeing that it is the intention of several of the leading medical schools in this country and in Great Britain to infiltrate their teaching with public health information in such a manner that no course is taught, no specialty considered without inclusion of the preventive information pertinent to each subject, he urges with Sir George Newman, the Chief Medical Adviser of the British Ministry of Health, that it is the duty of every medical practitioner to be conscious of this responsibility and to act always from the viewpoint of preventive medicine as the representative in his district of the interests of the community. Further, by virtue of the authoritative position which he occupies in advising them as to the regulation of their daily lives, he constitutes, perhaps, the most important single influence in the delicate and difficult problems of public health education.

It is now in domestic and individual hygiene that the future of preventive medicine will be to a large extent; individual hygiene, dealing, for example, with such intimate questions as venereal disease, and domestic hygiene, dealing with the housing problem.

The physician obviously will be the adviser in such matters more than ever before. As Professor Zinsser states with absolute truth, he who engages in the pursuits of medicine becomes thereby a public servant. The nature of his work has forged his chains and it is his lot to interpret and persuade.

THE SPLEEN

About that of which little is known much is written. Certainly much has been written about the spleen and but little seems as yet to be known concerning its essential function.

The ancients considered the spleen a seat of the passions, hence the expression to "vent one's spleen." Just where it was discharged is much to be guessed, though doubtless through its conspicuous vessels and into the blood (or vital fluid) stream. This, however, was internal and the venter must have benefited more than the bespleened, the person who aroused his wrath, suffered. The spleen was considered a source of melancholy, though old Robert Burton was catholic enough to guess that melancholy might arise from the misbehavior of any organ of the body.

To the clinician the enlargement of the spleen in certain diseases is one of the facts of experience, but this enlargement is by no means explained. Occurring in connection with infection by parasites, it might seem that this organ had for its chief occupation the handling of such organisms, though we believe this theory has never been advanced with any assurance and it is more likely that it is appropriated as a dwelling place by the invaders.

We know that we can get along without the spleen and that its removal is accompanied with comparatively little disturbance, but this only deepens the mystery of its presence. A few years ago the physiologists were content to call the spleen the graveyard of the blood corpuscles, but the organ has fascinated them by its apparent uselessness, and a number of investigations have been going forward recently on its account. Among the theories put forward by only two students are: it may have something to do with the formation of uric acid, it may have something to do with hemolysis, it may have to do with the metabolism of calcium, and it may be a large lymphatic gland.

Bancroft of Cambridge finds that the spleen varies greatly in size in the living and in the dead experimental cat. In the former it is four times larger and he believes it serves as a reservoir, adjusting the amount of blood to the work of the body, particularly in connection with the need for more oxygen carrying capacity. When cut away from its nerve connections it does not so function. Seemingly the ancient and the modern theories confirm each other, for when one "vents" his spleen in the old way there is

always a firing up of the organism and consequently a concomitant need for oxygen. It will be interesting to look forward to the results of further study on the subject of the physiology of this organ. Certainly it will be kept busy meanwhile in doing everything that physiologists have surmised it to be capable of accomplishing.

INTESTINAL OBSTRUCTION

Intestinal obstruction seems to have increased within recent years as a cause for operation and of mortality. After a certain age its occurrence is fairly frequent and its results are too often fatal. In the *Boston Medical and Surgical Journal,* April 23, 1925, Dr. Howard K. Tuttle, of the Ancon Hospital, discusses the mortality of intestinal obstruction from his experience of one hundred and fifty cases coming to operation or autopsy. The object of the paper is to determine if possible how the excessive mortality rate may be reduced.

It is pointed out that it has been learned from animal experimentation and operating room observation that toxic substances are formed in the proximal segment of the blocked intestine, that the higher the obstruction the more toxic are the substances, that this toxic material is not readily absorbed through a normal mucosa but as soon as distension and consequent interference with the circulation occurs absorption in overwhelming doses follows. Death in various forms may result from this septic absorption and treatment to be effectual must be so directed as to prevent the occurrence of any condition which threatens life and according to Tuttle the only method is by early surgical interference.

There is, of course, no doubt that in these conditions, as in practically all conditions in which reliance must be placed on operation, this treatment is delayed too long. And it is not always delay on the part of the patient that is at fault, but, as Tuttle shows, delay and procrastination on the part of the surgeon may be the cause of excessive mortality in acute intestinal obstruction.

The author thinks that acute intestinal obstruction follows appendectomy more often than any other abdominal operation and he advises that suppurative cases are best drained along the posterior parietal peritoneum by a McBurney incision close to the anterior superior spine even though the abdomen has been opened through the right rectus muscle or in the midline. However, while there are many precautionary measures to be taken during and after operation which tend to render it safer, after all the best chances of success lie in early diagnosis and prompt surgical intervention. Tuttle holds that operation is indicated even when intestinal obstruction is suspected, as by operating on early symptoms and physical findings it may be found occasionally that intestinal obstruction does not exist but the death rate will be reduced substantially in those cases which if observed for another twenty-four hours all doubts as to diagnosis will have disappeared.

Early operation is easy and comparatively safe while late operations are in a high degree dangerous. Therefore it is urged it is better to take some risks of wrong diagnosis than to leave the case until operation is hopeless. Also be it noted it is remarkable with how great rapidity postoperative cases can develop into what are practically obstruction cases beyond the skill of the surgeon.

DIET IN THE PREVENTION OF DISEASE

It has been stated by many authorities that diet is the cause of more disease and conditions of ill health than any other cause. Evidence has seemed to accumulate to show that the diet of civilization is especially prone to cause disease. An indictment has been framed against much of the food eaten in modern life on scientific and clinical testimony. It has been observed that diseases of various kinds follow the consumption of certain foods even when eaten in moderation.

Clinical observation and science have gone hand in hand in the attempt to solve the problem of diet in relation to disease. In this country the science of dietetics has made the greatest progress and, perhaps, the majority of medical men of the present day here learn something of the therapeutics of food and drink in their student days. In some countries little attention is paid to the subject while in others it languishes.

With the praiseworthy object of arousing interest in the matter, the controlling editor of the *Practitioner* collected a series of papers from distinguished British authorities on diet which were published in the January number. Several of the papers are given over to the consideration of the vitamines and these are verbally analyzed and discussed in the most thorough manner. Sir William Wilcox deals with dietetics, vitamines and food reform, emphasizing the point that the public in mass are profoundly ignorant of food values and of the dangers lurking in food from various viewpoints and that public opinion sadly needs education in this direction. Professor F. Gowland Hopkins, professor of biochemistry in the University of Cambridge, a pioneer in biochemical research, points out the criteria of an efficient diet and explains clearly, exactly what is known of the vitamines and the limitations of our knowledge in this respect. He shows that what definitely emerges from modern research is the

truth that diet may be faulty when it is abundant, and that ill health may arise from ill nutrition much more frequently than seemed likely when the criteria applied to foodstuffs referred to quantity and digestibility alone.

Professor Plimmer, professor of chemistry in the University of London, deals with vitamine problems in nutrition, somewhat exhaustively pointing out among other valuable facts that under all variations of vitamine shortage experimental animals are more susceptible to infections of all kinds. A very instructive paper is contributed by Dr. John Boyd Orr, director, Rowett Research Institute, Aberdeen. Dr. Orr attributes most of the dietetic ills which inflict mankind to ill balanced mineral metabolism, and draws attention to the bad effects which follow deficiencies in a diet of calcium, phosphorus and iodine. Deficiency of iodine in the vegetation is believed to be the cause of athyreosis in certain inland districts in North America. Also he alludes to the prevention of simple goitre by the administration of iodine, although he is careful to note that the correlation between the deficiency of iodine in the vegetation on drinking water to goitre has not been definitely established. He refers to the predisposition to infectious diseases which is a feature of defective mineral metabolism among animals. Iodine deficiency accompanied by a depletion of the thyroid of this element appears to be associated with decreased reaction to certain toxemias. In tuberculosis there is usually a negative calcium balance presumably as a result of an abnormal metabolism due to the toxemia.

Dr. Leonard Williams, a trenchant writer, indicts present day foods of civilization and the methods of preparing the same in a paper entitled The Scandal of Present Day Dietetics. He deplores the ignorance on the subject of the medical profession and the laity and almost suggests that dietetics should be made a compulsory subject for medical students, and thinks that the present overburdened curriculum could be lightened profitably by sacrificing some of the pharmacological and other superfluities which in his opinion do much present harm by creating a fake atmosphere. His argument is that if young medical men were turned out thoroughly equipped in the principles of rational physiological feeding, their knowledge would quickly permeate all classes of the community and the present ignorance in action would be replaced by science in operation. Dr. Williams takes a tilt against the kind of meat and sugar we eat and indeed finds little to be said in favor of our present day diet. Moreover, he is an avowed and strong believer in uncooked food as far as is possible and pins his faith on cheese, fresh uncooked vegetables and fruit. He takes the stand that people who eat natural foods never eat too much, because their palates are unstimulated, and their physiological needs quickly satisfied.

Dr. C. Henning Belfrage, who gives some practical hints on dietetics, is a believer in uncooked food, averring that vegetables and meat are generally cooked to death, so far as their vital elements are concerned. He holds that the nursery and school must be the focus of attention; food habits, like other habits formed in childhood, will tend to become fixed for good or ill.

Dr. N. Mutch shows the relationship between diet and toxemia, pointing out *inter alia* that the practice common among certain sections of the community of mincing the cold remains of the Sunday's joint and recooking it later in the week is a fruitful cause of food poisoning. Lieut. Col. McCarrison, I.M.S., tells of his experience of the effect of various diets in different parts of India. Lieut. Col. Hallilay also writes of diet in India; both these papers are illuminating and are calculated, perhaps, to cause a revision of some of the established tenets with regard to the effects of diet.

In considering the question of diet some of the points which appear to be overlooked are that both climate and occupation profoundly influence the effects of diet. A strong, vigorous man working out of doors in the fresh air needs a different kind of food to one who works indoors and to one engaged in a sedentary occupation indoors. Climate again has a distinct bearing on the subject and the personal equation and individual idiosyncrasy must not be lost sight of. However, when all allowances have been made it seems that regarding the matter from a broad outlook that the diet of civilization fails in several essential features and that reforms in this direction will be to the advantage of the community at large. Education is required with respect to many unsettled points of the diet problem and it is the medical profession which must educate the public to eat wisely and well.

NATIONWIDE RECREATION

The development of the spirit of sport and fair play through games and outdoor diversions, and above all of health, tending to the making of good citizens, are perhaps the chief reasons for organized recreation. That this need of our urban dwelling nation is becoming more and more recognized was shown at the National Conference on Outdoor Recreation, held in Washington last May, where it was reported that in more than four hundred of our cities of more than eight thousand population no provision whatever is made for playgrounds, and the same is true of the congested sections of many of our larger cities.

Mr. Theodore Roosevelt presided at the conference, which was attended by many of the cabinet officers and other Government officials, as well as by representatives from many organizations interested in a nationwide recreational movement. Among the problems discussed were the widest possible practical extension of recreational facilities, the contribution of recreation to the development of the individual citizen, the employment toward this end of our parks, forests and other public reservations, national, state and local, to their fullest extent, and the necessity of taking means to preserve what is left of our fast disappearing wild life.

Among addresses at the conference, that of Major William A. Welch outlined some of the things New York is doing to promote enjoyment and profit from outdoor life.

Dr. William A. Hornaday, director of the New York Zoological Park, told of the five million five hundred thousand hunters who go out each year to kill all the game they can find, and prophesied the production in the not far future, if present conditions are allowed to persist, of a devastated country with treeless slopes and mountains, forests reduced to stumps, drained mud flats instead of lakes, poisoned streams, and an utter lack of wild life. The president of the Izaak Walton League spoke of the peril of draining such large areas as are under operation today, for thus the waterfowl are deprived of their homes and breeding places, the migratory birds of their great highways, and the warm water game fish of their last stand for existence.

Pleas were made for the protection from any form of desecration and putting to commercial uses of our present eight million acres of national parks, for the extension when practical of these, and of similar state and local reservations, for the satisfying of perhaps our greatest national need along this line—the provision of many more city parks, town forests, school playgrounds, open squares and the like; for all these add to the joy and fullness of life in serving as museums of noble scenery and wild life, in providing recreational resources, and protecting the water supplies of towns and cities.

The conference effected the organization of a permanent National Council of Recreation, the purpose of which is to survey the whole field, outline practical policies, serve as an exchange bureau of information on the subject, recommend further organization when and where necessary, and foster and plan the cooperation of governmental and private agencies, all to the end of inspiring an acquaintance and intelligence interest on the part of the public with the pleasurable and beneficial aspects of outdoor recreation, and of providing and maintaining in all localities the resources for such enjoyment.

QUEEN ELIZABETH'S DOCTOR

In the Elizabethan era it was the custom for doctors to compound and sell their most valuable medicines. The common drugs were sold to the patients by the apothecaries, who were little more than grocers, though it happened sometimes that an ambitious apothecary would pick up enough information about herbals and empirical compounds to vie with the ignorance of doctors of those days.

Dr. William Bulleyn, physician to Queen Elizabeth and author of *The Book of Simples* and *Dialogue Between Soarnes and Chirurgi,* gave the following rules for an apothecary's conduct: "Must fyrst serve God, forsee the end, be clenly, pity the poore. Must not be suborned for money to hurt mankynde. His garden must be at hand with plenty of herbes, seedes and rootes. To read Dioscorides, to know ye natures of plants and herbes. To invent medicines, to chose by coloure, tast, odour, figurie, etc. That he may open wel a vein to help pleuresy. That he delyte to reede Nicolaus Myrepsus, Valerius Cordus, Johannes Placaton, the Lubik, etc. To remember his end, and the judgement of God: and thus I do commend him to God, if he be not covetous or crafty, seeking his own lucre before other men's help, succour and comfort."

The Queen gave her physician £100 per annum and diet wine, wax, etc., as perquisites, and her apothecary's bill of which some of the items were: A confection made like a manus Christi, with bezoar stone and unicorn's horn—eleven shillings. Rosewater for the King of Navarre's ambassador—twelve pence. A conserve of barberries with preserved damascene plums, and other things for Mr. Ralegh—six shillings.

Pearl mixtures were very popular among the more wealthy patients; we may presume that Bulleyn's recipe for Electuarium de Gemmis would be extra to his yearly stipend! Here is the recipe: Electuarium de Gemmis.—Take two drachms of white perles; two little peeces of saphyre; jacinth, corneline, emerauldes, grannettes, of each an ounce; setwal, the sweate roote doronike, the rind of pomecitron, mace, basel seede, of each two drachms; of redde corral, amber, shaving of ivory, of each two drachms; rootes both of white and red behen, ginger, long peper, spicknard, folium indicum, saffron, cardamom, of each one drachm; of troch, diarodon, lignum aloes, of each half a small handfull; cinnamon, galinga, zurabeth, which is a kind of setwal, of each one drachm and a half; thin peeces of gold and sylver, of each half a scruple; of musk, half a drachm. Make your electuary with honey emblici, which is the fourth kind of mirobalans with roses, strained in equall partes, as much as will suffice. This healeth cold diseases of ye braine, harte and stomack.

News Items.

Hospital Directory.—A list of hospitals and fixed clinics in New York city with transportation guide, has been issued by the New York Academy of Medicine. Three maps are included in the volume.

New Municipal Hospital.—The city administration is taking steps to acquire a site and erect a $1,200,000 hospital, with accommodations for one hundred beds, in the southern part of Bronx, to take the place of the Lincoln Hospital.

Columbia to Take Over Patents.—Columbia University is to take over patents for discoveries made in its own laboratories, in order to protect the inventor and the public, and to enable the university to share in the profits for the promotion of research.

Delegates to British Meeting.—Dr. William D. Haggard, president of the American Medical Association, Dr. George E. DeSchweinitz, of Philadelphia, and Dr. Howard Fox, of New York, have been appointed delegates from the American Medical Association to the British Medical Association meeting, to be held in July, at Bath, England.

Industrial Hospitals.—The Manufacturers' Association of New Jersey announces that it intends to establish six hospitals to provide "more efficient and less expensive medical treatment" for injured workmen. These hospitals will be established in Newark, Paterson, Trenton, Jersey City, Camden, and some other city. A company known as the New Jersey Manufacturers' Hospitals, Inc., has been formed. According to newspaper reports, this move has been due to increased medical fees.

New York Tuberculosis Society.—At the annual meeting of the New York Tuberculosis Association, figures were presented showing a fall of three per cent. in the mortality rate in 1924, the rate being 93 in 100,000, which may also be compared with a rate of 196, ten years ago. In some parts of Brooklyn a rate was reported as low as 39. Tuberculosis is now fourth instead of first in the city's death list. Officers elected at the meeting were: Dr. James Alexander Miller, president; Mr. Homer Folks, vice-president; Dr. Nathan E. Brill, secretary, and Mr. Thomas W. Lamont, treasurer.

Thromboangiitis Obliterans Study.—The recently organized committee for the study of thromboangiitis obliterans, of which Dr. Reginald H. Sayre is chairman, and Dr. Benjamin Jablons, vice-president, has appointed subcommittees for ways and means of obtaining funds, for preparing a questionnaire to ascertain frequency of the diseases and methods of treatment, for research into the etiology of the disease, and for study of its clinical aspects and differentiation from simulating affections. A contribution of five hundred dollars has been received from Mr. B. M. Maltz of Brooklyn, who has been a sufferer from the disease.

Travel Study Club of American Physicians.—The Travel Study Club of American Physicians at its ninth annual reunion, reelected Dr. Louis Livingston Seaman and Dr. Richard Kovacs of New York respectively as president and secretary-treasurer; Dr. Edward B. Heckel, Pittsburgh, Pa., Dr. J. P. Lord, Omaha, and Dr. F. H. Albee, New York as vice-presidents. The club has decided on a 1926 study tour to London, Paris, Switzerland, Munich, Vienna and Berlin. Participation in this tour will be limited in number and restricted to members and medical friends recommended by them.

Venereal Disease.—The Division of Venereal Diseases of the New York State Department of Health will hereafter be called the Division of Social Hygiene. It is felt that the educational activities of the division have been handicapped by the former title.

A special meeting of male employees of the Atlanta, Birmingham, and Atlantic Railway Company was recently held in Fitzgerald, Georgia. The company issued free transportation for over six hundred, and fully twelve hundred people attended the meeting. The meeting was arranged by the Georgia State Board of Health, and Dr. W. H. Gillette of the Public Health Service delivered an illustrated lecture on sex education and venereal disease.

The General Federation of Women's Clubs arranged an exhibit on social hygiene in connection with the conference of the International Council of Women, recently held in Washington.

Research in Foot and Mouth Disease.—Dr. Peter K. Olitsky of the Rockefeller Institute, Jacob A. Traum, D.V.S., University of California, and Dr. Harry W. Schoening of the Bureau of Animal Industry have been selected by the U. S. Department of Agriculture to conduct research in Europe on the foot and mouth disease. Studies will be made in Berlin, Budapest, and Alfort, France.

Institute of Public Health.—Earle B. Phelps, formerly of Massachusetts Institute of Technology and the Hygienic Laboratory of the Public Health Service, has been appointed head of the department of sanitary science of the Institute of Public Health of Columbia University, founded under the will of the late Joseph De Lamar. Dr. Haven Emerson is head of the department of public health administration, the first group to be started.

East Side Clinical Society.—A new society, known as the East Side Clinical Society, has been formed, unique in character, as only cases, instruments, and specimens are presented. The officers are: President, Dr. Joseph Van Den Berg; first vice-president, Dr. Hyman Goldstein; second vice-president, Dr. Rubin A. Gerber; corresponding secretary, Dr. Jacob Daley; recording secretary, Dr. Joseph Salan; and treasurer, Dr. Ralph L. Dourmashkin.

Annual Health Officials Conference.—Health officers and public health nurses of New York state will hold a conference at Saratoga Springs, June 23d to 25th. The conference will be opened by Dr. Mathias Nicoll, Jr., commissioner of health, and addresses will be made by Governor Smith, Dr. J. W. S. McCullough, chief health officer of the Ontario Provincial Department of Health, and Dr. Nathan B. VanEtten, president of the New York State Medical Society.

Society News.—The American Psychopathological Association has elected the following officers: Dr. Smith Ely Jelliffe, New York, president; Dr. Ross M. Chapman, Towson, Maryland, and Dr. Edward J. Kempf, New York, vice-presidents; Dr. Sanger Brown, 2d, New York, secretary, and Dr. William C. Garvin, Binghamton, New York, treasurer.

The American Urological Association has elected the following officers: Dr. John R. Caulk, St. Louis, president-elect; Dr. Homer G. Hamer, Indianapolis, secretary; and Dr. James B. Cross, Buffalo, treasurer.

The American Gynecological Society elected the following officers at its recent meeting in Washington: President, Dr. Franklin S. Newell, of Boston; first vice-president, Dr. Hiram Vinberg of New York, second vice-president, Dr. C. Jeff Miller, of New Orleans; secrtary, Dr. Arthur H. Curtis, of Chicago; and treasurer, Dr. Charles C. Norris, of Philadelphia.

Personal.—Dr. Hideyo Noguchi of the Rockefeller Institute has been awarded the Kober Association Medal.

Dr. William S. Elkin, who has been dean of the Emory University School of Medicine, in Georgia, for seventeen years, has been elected emeritus dean and emeritus professor of obstetrics and gynecology. Dr. Russell F. Oppenheimer, superintendent of Wesley Memorial Hospital, has been appointed dean.

Dr. Norman Titus, of New York, is to serve as delegate from the American Electrotherapeutic Society to the International Congress on Radiology and Physiotherapy, to be held in London in July.

Dr. William A. White, of St. Elizabeth's Hospital, Washington, was the speaker at the graduation exercises of the Long Island College Hospital.

Dr. Haven Emerson, of New York, spoke on Periodical Health Examinations at a meeting of the Hudson County Medical Society, Jersey City.

Dr. Charles H. Frazier, of Philadelphia, spoke before the Brooklyn Surgical Society and the Medical Society of Bay Ridge, on trigeminal neuralgia, presenting several patients.

Dr. J. F. Montague, of New York, spoke before the Aesculapian Society of Philadelphia on Pruritus Ani demonstrated by motion pictures.

Dr. Channing Frothingham, of the Harvard Medical School, spoke on Classification and Treatment of Acute and Chronic Nephritis, at a joint meeting of the honorary medical society Alpha Omega Alpha and the Syracuse Academy of Medicine, May 20th.

Dr. Walter T. Dannreuther, formerly associate professor, has been made professor of gynecology in the New York Post-Graduate Medical School and Hospital.

Foreign Correspondence.

LONDON LETTER

(From our own correspondent)

LONDON, *May 14, 1925.*

DISCUSSION ON ENDOCRINE THERAPY

A special discussion on endocrine therapy was opened at the Royal Society of Medicine, London, on March 31st. Dr. Langdon Brown dealt with the subject from the clinician's point of view. He said that there were five methods of administration of endocrine substances. The oral method was very uncertain except in a few cases of pituitary administration, in which it was difficult to exclude the element of suggestion. The nasal method was originally investigated as a result of the suggestion that this might be a more advantageous route for pituitary preparations since the pituitary itself was an outgrowth of the nasal mucosa. A fair degree of success had been obtained in the treatment of diabetes insipidus in this way, and there was a possibility that adrenalin also might be absorbed by this route. Rectal injection had had a measure of success in selected instances, but subcutaneous injection remained the most effective method of introducing all the substances concerned. Grafting and transplantation were still on trial; the ingrafted material was treated as a foreign body and absorbed so that the action could be but temporary. The results seemed to be better if the graft were placed in some homologous tissue, as, for instance, the insertion of adrenalin grafts into the testis, which method had been known to produce a continued life in the graft for over two years.

It would be of great advantage if some biochemical tests could be devised to form a standard for investigation of the action of these substances; at present there was only the basal metabolic rate and the blood sugar. The difference of opinion between the clinician and laboratory worker was partly due to the credulity and overreadiness of the former to acclaim untried therapeutic agents and partly to the fact that the laboratory worker was able to reduce his problem to the simplest possible terms, so that he was liable to forget the much more complicated and delicate adjustments with which the clinician had to deal. Scepticism had even gone so far as to deny the interactions between the endocrine and autonomic nervous systems, but there seemed little doubt that the cooperation between the adrenal, thyroid and pituitary glands on the one hand, and the pancreas and the parathyroid on the other, and their mutual antagonism, was supported by a considerable body of experimental evidence.

It must be admitted, however, that if polyglandular therapy had a rational basis it was often irrationally applied. The thyroid was the gland most widely and easily administered; the original doses were now known to be too large. It was of value for children who showed a failure of growth, nocturnal enuresis, night terrors, ligamentous relaxation, etc. Parathyroid had a great function as a catabolic agent; if its normal secretion were diminished there was an accumulation of waste tissue in the body. It could be absorbed when given therapeutically, producing a great rise in the calcium content of the blood. Adrenal substance seemed to be of little use in substitution therapy; its value lay in its pharmacological action as a local anesthetic and hemostatic, in the reduction of spasm and in asthma. It seemed that pituitary might be absorbed by the stomach, but its value as a substitute was doubtful; it might relieve the symptoms of Frőhlich's syndrome and of adiposity, and it was valuable in diabetic conditions and as a stimulant to plain muscle and heart muscle. The use of insulin in diabetes was proved, and the impression that its administration must be for life should be strongly contradicted; many patients were able to return to normal life without the continuance of the drug. Ovarian extract had also proved its value, but the present preparations were not wholly satisfactory. It must be free from corpus luteum and might be of value in thymic asthma and transient glycosuria. Orchitic substance was more doubtful; it was as yet too soon to judge of the value of the grafting methods introduced recently.

Mr. Leslie Pugh, a veterinary practitioner, said that the use of endocrine substances in veterinary work did not differ materially from that in medical work. Pituitary was used in obstetrics and thyroid in a variety of conditions. Corpus luteum extract had been used for sterility in cattle. Insulin had been used for the hyperglycemia and ketosis of cattle.

Mr. Kenneth Walker confined his remarks to the effects of testicular extract and grafts. It might be said quite definitely that the oral administration of testicular extract was absolutely useless; all experiments had been negative. Experiments with grafting were rendered difficult by the scarcity of material and the necessity for careful technic to insure vascularization. Voronoff claimed valuable results from his work on the testes of apes, but it seemed that the improvement was either in the nature of an increase of muscular and mental vigor and general well being and growth of hair than any specific action on neurasthenia or sexual disabilities. Mr. Walker himself had done transplantations with human material used much the same technic as Voronoff and implanting the graft in a serous cavity where it was nourished by the rich exudate until vascularization could take place. In his experience the grafts survived for two or three months but there was degeneration of the tubules into cords and the cells repressed to an embryonic condition. Death of the graft did not necessarily mean loss of all the benefit. It might be that the secretion supplied by it tided the patient over a critical period while the compensatory function of the other glands was being established. It must not be forgotten that the testis was seldom the whole seat of the trouble; there was a reciprocal involvement of other glands and structures which could not be affected by a graft. The operation of ligature of the vas deferens led to marked sexual excitement and increase in the interstitial cells of the testis. Steinach's results were impressive, as the life period was undoubtedly increased in rats, although relapse occurred inevitably sooner or later. In man the results were much less certain; in some cases there seemed to be no benefit, in others an improvement in the general health. It was by no means certain that the internal secretion of the testis came

rom the interstitial cells, but this did not nullify the experiment. Mr. Walker had himself done fifteen such operations, and although it was difficult to eliminate the element of suggestion it seemed that there had been improvement in thirty to forty per cent. He advised the operation in paralysis agitans, as two out of five cases he had operated upon showed marked benefit therefrom.

Mr. H. Crichton-Miller pointed out the importance of the endocrine gland secretions from the subjective aspect. There was much need for evidence as to their effects for functional sufferers especially. He and the staff at his clinic were about to make experiments on the subject. Some members of his staff and medical volunteers would consume certain tablets and report results.

Mr. J. E. R. McDonagh spoke of the effects of those glandular extracts with which he had experimented on animals—i. e., adrenalin, thyroxin, insulin and ageratin (testicular extract). His object in this research was to ascertain the effects of drugs on the blood and organs and so to arrive at a basis for their chemotherapeutic employment in man. Many of the extracts were derivatives of the amino acids. Though the amino was the most active group, the action of the compound depended really on the way in which this group was checked. Adrenalin caused the protein particles in the plasma to increase in number, and then to go into solution, and this dual action of conduction and dehydration caused constriction of capillaries and a consequent rise of blood pressure.

The action of adrenalin was not specific, he said. Insulin caused hydration of the protein particles, and adrenalin proved to be an antidote because it caused dispersion of the hydrated particles. When protein particles increased in size they were likely to be precipitated in capillaries, and if in the cerebral ones, fits and convulsions ending in coma ensued; while when this took place in the lungs there was the pulmonary form of shock. Adrenalin was not powerful enough in these conditions, and it should be substituted by glucose injected intravenously and oxygen injected subcutaneously. Adrenalin was apt to fail as a styptic, because its later action of dehydration caused coagulation to be retarded. Thyroxin caused a slower dehydration of protein particles than adrenalin, hence it was more valuable in chronic diseases; in the chronic stages of disease the protein particles increased in size and became independent. In his view, malignancy was simply an expression of protein hydration. When the particles gradually increased in size, thyroxin could break them up. Its action could be enhanced by the simultaneous employment of colloid iodine. Insulin caused hydration of the protein particles, and its action was not specific; its effect could also be produced by certain synthetic organic preparations of sulphur. Insulin was an excellent antidote against any powerful dehydration. An acute bacterial infection might cause such profound dehydration as to call for insulin, the drug best suited to bring back to the colloidal state those protein particles which were passing into true solution. Insulin could also be employed with advantage in cases of anemia associated with a great destruction of the red blood corpuscles. With regard to operation, he said that he did not know anything of the chemistry of the compound, but its clinical behavior suggested that it might be a phosphatide, related to cephalin. Ageratin protected an animal against infections, interfered with the antigenic action of the organic extract in the Wassermann reaction, and reduced the precipitating effect of a positively reacting serum. When once in the system, this drug should prove useful in protecting man against the invasion of parasitic and chemical reagents.

Dr. M. B. Ray dealt with the many early beliefs associated with the influence of various foods and drugs on the health and endurance of the individual, and expressed his belief that the ductless glands exerted a powerful effect on the body metabolism. He pictured various types of cases which were held to be significant of deficiency of one or other of these important secretions, laying particular stress on the relation of goitre to rheumatism in young girls of ten to fifteen years of age. He said that in localities where goitre was endemic, the incidence of rheumatic fever, cardiac rheumatism, and rheumatoid arthritis was abnormally high.

Prof. Swale Vincent was pessimistic as to the value of the oral administration of preparations of the ductless glands with the exception of those of the thyroid. He deplored the lack of exact knowledge regarding the pituitary and adrenals and was not favorably impressed by the observations of Mackenzie Wallis on the blood sugar curves, and he was unfavorably impressed by those of Prof. Dixon. Much more scepticism was needed by the practising physician on these matters. One never knew what would happen if a certain treatment was not adopted, and until the normal curve and incidence of a disorder was known, it was dangerous to assume that a certain remedy given had been efficient, and it was especially dangerous to give a mixture, as was often done, and attribute a result to one particular component of that mixture. There were many pitfalls in therapeutics, and in endocrinology more than in any other department.

RICKETS AND DIET

A section of the medical profession here told that rickets is caused by lack of sunlight and unhealthy environment and ignore almost wholly the factor of diet. In the *London Times*, April 13th, a correspondent points out that owing to better and more suitable food, the manifestations of rickets in London are less obvious than formerly. He goes on to join issue with those who take the stand that rickets is not a dietetic disease and draws attention to the fact Professor Mellanby has demonstrated that diet is the fundamental basis of rickets which conclusion was confirmed by the investigations of Miss Harriette Chick and a British staff who were sent by the London Lister Institute and the English Medical Research Council to Vienna after the war and who pursued their researches there for a period of three years. It seems as Dr. Eric Pritchard, director of the Infants' Hospital in London, and others believe that diet, lack of sunlight and unhealthy environment all play parts in the production of rickets, and that to state dogmatically that want of light, bad housing and unhealthy surroundings are the sole causes is to argue against ascertained facts.

A NEW BOOK ON CANCER

A useful little book on cancer has been published recently by Kegan Paul, London, G. P. Dutton & Co., New York. It is entitled *The Conquest of Cancer,* is written by H. W. S. Wright, M.S., F.R.C.S., with an introduction by F. G. Crookshank, M.D., F.R.C.P. The introduction is informative in a high degree and explains much about the disease which is overlooked or ignored. Mr. Wright stresses the importance of early diagnosis, stating that this is by far the most important factor in the cure of the disease and claims that if the public were educated to the point that each individual took as great care to prevent cancer as he does to prevent dental sepsis, ninety per cent. of the cases of cancer would be prevented. It must be borne in mind that education of the public with regard to care of the teeth developed slowly, at any rate, in this country. By persistent efforts there is no reason why similar results should not be brought about in the case of cancer.

Letters to the Editor.

THE VENEREAL PROBLEM IN ENGLAND

To the Editor: LONDON, W. I., *April 21, 1925.*

As some Americans are still under the delusion that London has something to teach New York in the matter of the management of the venereal problem, it would be well at this stage to record the bare facts of the case, as they appear to an independent lay observer like myself, who has been resident in England continuously for several years.

1. In England voluntary treatment at public expense is provided for men, women and children, innocent and guilty alike. It is officially claimed that this provision reduces the number of persons suffering from disease. Hence that it is a form of prevention as well as cure.

2. Undoubtedly the system does clear up a large number of sources of infection, and thus save much danger and misery to the individual and to the community. But the majority of these free patients (sometimes from sixty to seventy per cent. of them) fail to continue attending long enough to be cured or even to be rendered noninfective; and there is no official followup system, no compulsory notification, and no compulsory treatment in England.

3. More fresh infections and late cases were recorded at the free clinics during the years 1919-1921 than during the years 1922-1924. But the first three year period included many "war cases"—soldiers demobilized while still infective and diseased, some of them comparatively late cases, and their "contacts" (innocent women and children and others).

4. Some patients now continue their attendances for longer terms than previously, thus slightly improving the community's chance of obtaining protection in exchange for heavy expenses incurred. These attendances are swelled by the inclusion of "incurables" and "chronics." In any case the free treatment system is now claiming more—not less—professional service. This is quoted as an "improvement."

5. There is a growing opinion among medical practitioners and the intelligent responsible lay public that the provision of free voluntary treatment for venereal diseases for all and sundry, leads to the neglect of sexual cleanliness and of selfdisinfection and to the encouragement of further risks. It has been found that some clinics are used by habitual libertines who report for early treatment of gonorrhea, returning two, three and even four times with fresh infections.

6. The policy of the Ministry of Health is to provide treatment and prohibit prophylaxis—for ecclesiastical and political reasons; and this policy is bolstered up by subsidizing the National Council for Combating Venereal Disease. This is a political society which receives annually from the Ministry of Health thousands of pounds on condition that it advocates the policy of early treatment rather than prophylaxis. A medical society (the Society for the Prevention of Venereal Disease) which endeavors to teach the public to rely on prophylaxis rather than treatment is denied all financial aid.

7. The Government subsidy to the National Council is expended partly in advertisements in the newspapers and magazines, which advertisements the council threatens to withdraw if the editors of the papers or their contributors advocate selfdisinfection; thus English public opinion is "formed." Part of the subsidy is spent in salaries and other emoluments for a clique of medical and lay officers, who naturally work to protect their own jobs; and the remainder of the annual subsidy is expended in printing pamphlets very few people read or giving lectures very few people attend. Some good is probably done by encouraging diseased persons to seek treatment. Variety is added to the work of the National Council by occasional joy rides, called "Enquiries." These are useless investigations regarding the spread of Christian syphilization among the "heathen" in the West Indies or in the Far East.

8. Theoretically the Ministry of Health accepts the prophylactic station, but actually there are no prophylactic stations in England, either for men or for women. Preventive treatment is sought in a few cases at the free clinics. There is not teaching of selfdisinfection to those who have previously risked infection, nor even to those who have contracted disease. Thus the majority of those engaging in irregular intercourse or risking infection in marriage, being denied prophylaxis, trust to luck. A few careful ones buy rubber sheaths—if they can afford it.

9. Only the fringe of the venereal evil in England is being touched by the free clinics; other cases are treated by private doctors, by quacks, or not treated at all. The number of cases of syphilis treated at the clinics often exceeds the number of cases of gonorrhea, although we know there are approximately three or four times as many of the latter hence from three fourths to four fifths of the venereal disease cases in England are concealed, so far as the official returns are concerned. The number of diseased women (married or unmarried) receiving any kind of treatment is negligible. Thus many English homes are festering in secrecy.

10. In 1917 an act was passed by the British Parliament called The Venereal Disease Act of 1917. It was intended to stop quack tratment and the sale of quack remedies. Unfortunately the word "prevention" was inserted by some morbid fanatics and it slipped through Parliament. This subsection 2 of section 2 now reads as follows:

"On and after the first day of November nineteen hundred and seventeen a person shall not hold out or recommend to the public by any notice or advertisement, or by any written or printed papers or handbills, or by any label or word written or printed, affixed to or delivered with, any packet box, bottle, phial, or other inclosure containing the same any pills, capsules, powders, lozenges, tinctures, potions cordials, electuaries, plasters, unguents, salves, ointments drops, lotions, oils, spirits, medicated herbs and waters chemical and official preparations whatsoever, to be used or applied externally or internally as medicines or medicament for the prevention, cure, or relief of any venereal disease:

"Provided that nothing in this section shall apply to an advertisement, notification, announcement, recommendation or holding out made or published by any local or public authority or made or published with the sanction of the Local Government Board, or in Scotland and Ireland the Local Government Board for Scotland and Ireland respectively or to any publication sent only to duly qualified medical practitioners or to wholesale or retail chemists for the purpose of their business."

11. The public discussion of this subsection, and the various official and unofficial interpretations of it, have stimulated quacks to new and most dangerous development of their business, as will be detailed later on.

12. In July, 1923, the Minister of Health (Mr. Neville Chamberlain) gave the following interpretation:

"I have been to the best fountainhead I could—the Law Officers of the Crown—and I have put to them certain questions as to the exact meaning of the relevant Section of the Act of 1917. I find that their view does not coincide with

that which is so commonly held by chemists, or that which was assumed to be the case by the (Trevethin) Committee. I asked the Law Officers whether anything in the Act prevents a chemist from selling disinfectants for the prevention of venereal disease where no written or printed instructions are affixed to or delivered with the disinfectant. The answer was brief and categorical; it was 'No!' I asked them again whether the second subsection of section 2 permits a chemist to give verbal recommendations of simple preparations intended to be used or applied for the prevention of venereal disease, and the answer was 'Yes! provided that no written or printed paper or label accompanies the verbal recommendation.' . . . Today a chemist may verbally recommend to a customer such preparations for such purposes. What he may not do is to give any written or printed instructions, although he may give verbally such instructions to the customer. . . . I tell you these things today, and I tell them to you with intention. There is no reason why you should not make them known."

Later on Mr. Neville Chamberlain added:

"First of all, it is clear that it would require an alteration in the law to permit the chemist to give printed or written instructions, and *personally I think that if these things are to be sold printed or written instructions should be supplied with them.*"

Still later on Mr. Neville Chamberlain said:

"I feel compelled to make a further observation in consequence of what you have said. I should not like anybody here to be under any misunderstanding. I am quite determined in my own mind that the Ministry of Health shall have nothing whatever to do with prescribing the composition of any remedies that may be made up, or give the instructions. I am going to keep the Ministry of Health quite outside that. Some outside competent authority will have to do that; but it will not be done here."

These statements were made to Deputation of the Society for the Prevention of Venereal Disease, which sought provision for the sale of prophylactic packets in the chemists' shops—with suitable printed instructions for selfdisinfection.

13. The result of this interpretation is that chemists and quacks are now selling at high prices "pills, capsules, powders, lozenges, tinctures, potions, cordials," etc., for the prevention of venereal disease. This nefarious trade is steadily growing under the shadow of the Ministry of Health. The wholesale manufacturers of these goods are claiming that the proviso of subsection 2 of section 2 of The Venereal Disease Act quoted above enables them to send printed advertisements "to wholesale or retail chemists for the purposes of their business," and the retail chemists and druggists and quacks are claiming that Mr. Chamberlain's interpretation enables them to sell, e. g., mercury pills at a guinea a box for the prevention of syphilis, and sandal wood oil capsules at half a guinea a box for the prevention of gonorrhea.

14. It has been found quite possible to exploit the ignorance and gullibility of the English public in this way, partly because of several years of official misleading based on the deliberate and sustained confusion of prevention and cure. The Ministry of Health maintains that cure *is* prevention; and that is all the quacks are doing—selling alleged cures for the prevention of disease. The public is very ready for this kind of misleading because by bitter experience many of them have learned that "cure" is not the simple and easy and rapid affair they have been falsely led to believe. They know that cure at the free clinics has proved to be difficult, prolonged, painful, and sometimes apparently impossible. Thus in desperation they try "swallowing something" when they have risked disease, or fear disease, or know they are suffering from it. They argue that if malaria can be prevented from occurring and recurring by swallowing quinine, why should not syphilis be prevented in the same way. Until the public are taught efficiently—taught collectively and taught individually—not only the mode of infection but also the mode of protection by quick selfdisinfection, they will never distinguish between "prevention" and "cure," and the community will never be saved from the occurrence in perpetuity of fresh cases of disease,—hereditary or congenital as well as acquired.

15. Although prophylactic packets with printed instructions are not on sale in England—but are prohibited, as already explained—such goods as calomel tubes are on sale without accompanying printed instructions. But the chemists do not consider that the few pence profit they make on these justifies them in assuming as a duty of supererogation the giving of free verbal advice to the public; and in any case many of them are not qualified to give reliable instruction in prophylaxis. As a business matter, it is much more profitable for them to accept the new quacks' charter which the Minister of Health has bestowed upon them, and sell more or less worthless remedies at high prices, and give no instructions with these, or just say that swallowing the pills, capsules, etc., so many times a day will "prevent disease."

16. There is reasonable ground for hope that as the sale of these quack medicines becomes more widespread still, in sheer desperation, the Ministry of Health will take its courage in its hands and either end or mend the present dangerous legislation. Then it will be possible to buy prophylactic packets in the London shops, with printed instructions, in the same way as in New York. But unless some competent authority assumes the responsibility for what is to be sold and what is to be said about it, London will still be behind New York, and other American cities where prophylactics are freely on sale, with officially or authoritatively approved printed instructions.

17. The spread of knowledge of selfdisinfection in England is at present almost completely suspended. The Society for the Prevention of Venereal Disease has accomplished very little in this respect and many of its members have become disheartened and retain merely a nominal membership. As a "free lance" I retain all my enthusiasm and earnestness, and all my conviction that in the end truth will prevail; and that the medical profession and the lay public will finally accept the fact that the only way to damp down and stamp out the venereal diseases is to control them in the same way as all other contagious diseases have been controlled and extirpated—namely, by the prevention of new cases—not by the treatment of old ones. The preventive method is being slowly and surely accepted in New York and other American cities. It is still rejected by London and other English cities. America has nothing to gain and everything to lose by paying any attention whatsoever to the misguidance of English officials and their subsidized societies and their morbid or misinformed moralists.

18. The English system has been on trial for nearly ten years, and the results are almost too horrible to contemplate. What England requires, first of all, is a complete revision of her present methods, and this revision cannot take place until there is, first, amendment or abolition of the venereal disease act 1917; second, establishment of a really qualified Royal Commission to consider the management of the whole problem of venereal disease; third, enactment of fresh legislation in accordance with the findings of that Royal Commission. Various official and unofficial "Enquiries" have been held in England during the last few years, but so far they have all proved abortive. No good has resulted from them excepting that gradually to some extent the public has acquired a conviction that all is not well; that venereal disease is being neither prevented nor cured by the present English methods, and that physical and moral deterioration is proceeding—perhaps at an accelerating pace. At any rate, the simple proposition that the way to prevent venereal disease is to *stop it before it begins* has not yet been accepted or realized, publicly or privately, in England; whereas I honestly believe that a little more earnestness, a little more enthusiasm, a little more confidence and publicity in regard to prophylaxis would put the American nation right behind this greatest of all efforts to ensure sexual cleanliness in ourselves and in our descendants.

I may mention, however, as a hopeful portent in England, the fact that the Freethinkers, through their official weekly journal and printing press, have backed up the spread of knowledge in regard to the medical prevention of disease. They have recently published a small book by myself entitled *Sexual Health and Birth Control,* which exposes the ecclesiastical domination of the Ministry of Health, and shows that the extirpation of the noncomformist conscience in England is a necessary preliminary to the extirpation of the venereal microbe.

ETTIE A. ROUT.

Book Reviews

PSEUDOAPPENDICITIS

Pseudoappendicitis. Study of Mechanical Syndromes of the Right Lower Quadrant Simulating Appendicitis. By Thierry de Martel and Edouard Antoine. Authorized Translation from the French, by James A. Evans, A.B., M.D. Preface by R. Bensaude. Illustrated with forty-one engravings. Philadelphia: F. A. Davis Company, 1925. Pp. 211.

At last we have a book that really gets at the bottom of the matter of pain in the right lower quadrant not relieved by appendicectomy. This work is a real contribution because it is based on the study of real cases and is not a hodge podge of active fancy and speculation. It is a pleasure to pay tribute to so thoroughgoing a study by French workers in the face of a tendency in some quarters to speak knowingly of "Gallic exaltation."

The outstanding virtue of this book from the viewpoint of style is clarity. The division of painful syndrome of the right cecocolon is into six groups: 1, Abnormally mobile cecum; 2, perivisceritis of the right lower quadrant with low cecum; 3, ptosis of the entire right colon; 4, Jackson's membrane; 5, perivisceritis of the right upper quadrant; 6, "double barrelled" right colon. Such a classification is exceedingly helpful.

The illustrations are silhouette cuts of radiographs and drawings. The use of the term "ascending cecum" is confusing.

In our opinion the book should be read and well digested by every internist and by every surgeon.

DYSENTERY AND PEPTIC ULCER

Enterogene Entstehung der Magen und Zwölffingerdarm-Geschwüre. Von Prof. Dr. Adolf Posselt. Sammlung zwangloser Abhandlungen aus dem Gebiete der Verdauungs-und Stoffwechsel-Krankheiten, IX Band, Heft 1. Halle a.S.: Carl Marhold, 1924. Pp. 55.

Posselt lays particular stress on the frequency of duodenal and gastric ulcers in patients who at one time or another had suffered from dysentery. Not only the toxic processes existing in dysentery, but also the cachectic state and the various pathogenic bacteria, are probably the cause of the development of the ulcerative lesions in the upper regions of the gastrointestinal tract. Spastic conditions, constitutional individualities, and anomalies of internal secretions are further factors in the origin of peptic ulcers.

THE MELTZER-LYON TEST

Diagnostic et Traitement des Maladies de la Vesicule Bilaire par l'excretion vesiculoire provoquee (epreuves de Meltzer-Lyon et De Stepp). Par M. Chiray et M. Milochevitch. Paris: Masson et Cie, 1924. Pp. 156.

Chiray and Milochevitch have given a complete description of the Meltzer-Lyon test for the diagnosis of gallbladder troubles. After perusing the literature on this topic they come to the conclusion that the dark bile obtained after the instillation of magnesium sulphate into the duodenum is derived from the gallbladder, as Lyon maintains. [This, however, is not yet a settled question. Reviewer.] The authors recommend Lyon's biliary drainage for the following conditions: 1, In chronic or subacute cholecystitis without stones; 2, in the chronic cholecystitis with stones, when these latter are quiescent, and there is a catarrhal inflammation of the biliary passage; 3, in acute cholecystitis complicating typhoid fever; 4, in atony of the gallbladder with spasm of the ampulla of Vater in duodenal ulcer; 5, in catarrhal obstruction of the cystic duct; 6, in all cases of chronic cholecystitis due to calculi, in which operations are contraindicated (like diabetes, severe heart lesions, nephritis, etc.). The book is well written.

SELFTREATMENT OF DYSPEPSIA

Dyspepsia and Its Selftreatment. By Jabu Nath Ganguli, B.A., M.B., Benares: M. B. Nath, 1924. Pp. 218.

This monograph instructs in a popular way the dyspeptic how to proceed. Acute conditions should be handled by the physician. Chronic cases, however, have to be taken in hand by the patient himself. "Be methodical and punctual in carrying out the instructions given. Method is orderly arrangement of things and works, and punctuality, its twin brother, is exactness in time. If you frame out a method of serving your body, and be punctual in ministering to its daily wants, recovery follows as certainly as day follows night." Ganguli takes much stock in fasting. He says, "Fasting is out and out the best physician in most stages of the disease, if judiciously resorted to." A fast at intervals and in length of time suited to the condition of the patient, is often successful in effecting a cure. On the contrary, indiscreet eating and drinking are like two thieves that come to the patient in the garb of friends to steal his health. Eat to live, but do not live to eat. Ganguli is also an advocate of prayers, and believes that praying to God helps to produce a cure.

RELATION OF LIVER TO ABDOMINAL INFECTION

The Liver and Its Relation to Chronic Abdominal Infection. By Charles Gordon Heyd, B.A.M.D., and John A. Killian, M.A., Ph.D. Structural Changes in the Appendix, Gallbladder and Liver from the Same Patient. By Ward J. MacNeal, Ph.D., M.D. Beaumont Foundation, Annual Lecture Course III, 1924. St. Louis: The C. V. Mosby Company, 1924. Pp. 165.

This little book, the joint product of the surgeon (clinician), biochemist and pathologist, is a good example of team work in medicine.

For the past few years Heyd has been removing bits of liver tissue from his laparotomized patients, particularly those suffering from gallbladder disease. He has thus learned that instead of being a pathological rarity, some form of hepatitis exists in all cases of chronic abdominal infection. Gallbladder trouble may therefore be regarded as an end stage, rather than an independent occurrence in a long series of changes involving the entire portal circulation. This lesson is well read and it should teach us that it is only by taking care of the organs draining into the portal circuit that we can prevent liver drainage and ultimate gallbladder localization. In this preventive program the surgeon plays a rôle, but by no means the entire rôle, inasmuch as the whole field of gastrointestinal hygiene and prophylaxis is opened up in this connection.

DIETETICS

Diet in Health and Disease. By Julius Friedenwald, M.D., and John Rühran, M.D. Sixth Edition, Thoroughly Revised. Philadelphia and London: W. B. Saunders Company, 1925. Pp. 987.

This standard book on dietetics is now in its sixth edition. Among the new matters included are sections on food poisoning, carotinemia, anaphylaxis, feeding of infants and children, celiac disease, diseases of the stomach and intestines, high blood pressure, nephritis, arthritis, postoperative diets, diabetes, deficiency disease. There have been revisions or additions to the tables of the salt contents of foods and weight, height and age. Professor McGlone has revised the section on the physiology of digestion and Dr. Gichner that on diabetes.

Locke's tables showing the composition of foods as actually eaten are included and are sure to enhance the book's value. There are still other additions, which together with those enumerated justify the statement in the preface that this single volume brings together "the greatest possible number of facts relating to food and nutrition in health and disease."

DISEASES OF THE RECTUM

Diseases of the Rectum and Pelvic Colon. By Martin L. Bodkin, M.D., F.A.C.S. Illustrated. Second edition, revised and enlarged. New York: E. B. Treat and Company, 1925. Pp. 487.

There are numerous good ideas scattered throughout this work, but on the whole the presentation is unfortunately inadequate. The English is not good, the style is careless and suffers heavily from lack of clearness. The discussion of colon irrigations and of constipation is unsatisfactory. The writer speaks of "the value of the rectum as a means of supporting life," and dismisses the subject of spastic constipation in a few colorless sentences. Neither in the section on examination of the feces nor in that on intestinal flora is the principle of the Schmidt intestinal diet even once mentioned.

As an evidence of carelessness in the getup of the book, it may be mentioned that one of the röntgen illustrations is printed upside down. It must be admitted that there are better books on diseases of the rectum and the pelvic colon.

HYGIENE

Grundzüge der Hygiene für Mediziner, Pharmazeuten und Ärzte. Von Dr. med. et phil. Max Eugling, Privatdozent für Hygiene an der Universität in Wien. Mit 131 Abbildungen. Berlin, Wien: Urban & Schwarzenberg, 1925. Pp. xvi-384.

This outline of the basic principles of hygiene is primarily intended for medical students, pharmacists, and physicians, but the style of presentation is so simple and the language so plain that it may well be recommended even to the laity.

The usual subjects discussed in textbooks on hygiene are discussed, such as the chemical composition of air, its gaseous contaminations, the foul air of close rooms, the dustlike elements in the air, moisture, air pressure and winds. Another chapter deals with the various kinds of climate. The heat economy of man is explained. Clothing and baths are discussed. The water supply is discussed and the cleansing and methods of sterilization of water are described. The various forms of food and their conservation are fully described. Special chapters are devoted to the hygiene of buildings and apartments, their heating, ventilation and illumination (natural and artificial). The disposal of waste matter is discussed. A chapter is devoted to the construction of special structures, such as hospitals, prisons, mass quarters and school buildings. The chapter on microorganisms and the methods used in their study are very precise. The chapters on infection and immunity and the subject of disinfection are well presented. There are also chapters on epidemics and their prevention. The chapter on the special microorganisms and infectious diseases is short and to the point.

The chapters on social hygiene and social welfare, on occupational hygiene, and on racial hygiene are all very practical and up to date. The book is extremely practical, and will be of special interest to the beginner in the study of hygiene.

INFLAMMATIONS OF LIVER

Les Hépatites Dysenteriques et leur Traitement. Par A. Valassopoulo et Pavlos Petridis. Preface du Dr. E. Rist. Paris: Masson et Cie, 1924. Pp. 143.

This excellent monograph deals with various forms of inflammations of the liver after dysentery, and also abscess formations in this organ as they are frequently encountered in the tropical countries, especially in Egypt. Valassopoulo and Petridis are great advocates of Roger's emetine treatment, as soon as a liver affection manifests itself in conjunction with amebic dysentery. The diagnosis of liver abscess is, at times, extremely difficult. Even an exploratory incision or puncture may fail to reveal pus, and still a small abscess be present. The authors advocate a thorough exploration of the liver and pleura by the Petridis method and thorough draining of the abscess.

The prognosis of liver abscess is grave, even after operation. Rupture of the abscess into the lungs, pleura, pericardium, gastrointestinal pericardium, gastrointestinal tract, and peritoneum are reported. In a few of these cases there was recovery.

ROOSEVELT HOSPITAL

Medical and Surgical Report of The Roosevelt Hospital, New York. Second Series, 1925, Based on the Work of the Years 1915-1924 Inclusive. New York: Paul B. Hoeber, Inc., 1925. Pp. xvii-378.

This report contains articles written by members of the hospital visiting staff expressly for this purpose, and also reprints of papers published in recent years in various medical and surgical journals. Twenty-two contributors are the authors of thirty-four articles, covering many fields of medical and surgical endeavor. The illustrations are quite numerous and well executed. The print is easily read. It is an excellent example of book making and the publishers are to be congratulated.

This book compares very favorably, from the medical and surgical viewpoint, with the other publications from certain clinics, which are deservedly very popular. This type of publication has this advantage over the more formal textbooks that they are intensely practical and usually more up to date. There was a time when such reports were published gratis. Now, that they are to be had only by purchase, they will probably be estimated according to their true worth.

THERAPEUTIC ANNUAL

L'Année Thérapeutique. Par L. Cheinisse. Anné 1924. Paris: Masson et Cie, 1925. Pp. 186.

This is the fifth yearly volume issued by the author as a summary of the therapeutic gleanings of the preceding year. While by no means an extensive work, it may be said to cover satisfactorily most of the new procedures which the general practitioner would have occasion to apply. A considerable number of the therapeutic measures recently advocated by American observers are included, for instance, insulin in preoperative and postoperative acidosis, benzyl benzoate in angina pectoris, convalescent serum in erysipelas, active immunization and serum therapy in scarlet fever, Coleman's diet in peptic ulcer, exsanguination transfusion in burns, etc. In addition, the reader familiar with French will obtain from the book a large number of other therapeutic suggestions, all acceptably presented and intelligently discussed. Among them are vaccine therapy in chancroid, milk injections in whooping cough, stovarsol in amebiasis, sodium borate in nervous dyspepsia, intraspinal casein injections in epidemic encephalitis, and sodium thiosulphate injections in gonorrheal epididymitis. These examples will suffice to show that the book is of the highest practical utility to the physician looking for some new procedures with which to oppose the commoner morbid states.

JAPANESE MEDICAL STUDIES

Mittcilungen aus der Medizinischen Fakultät der Kaiserlichen Universität zu Tokyo. Tokyo: Verlag der Kaiserlichen Universität, 1924.

Band XXXII, Heft 1, contains an article by T. Hayashi on experimental studies on the relationship between nephritis acidosis and the phosphorus and urea content of the blood. C. Aibara contributes an article on the effect of adrenalin on the blood picture of the rabbit and man, especially its value in the functional testing of the spleen. K. Sakaguchi, T. Matsuyama and M. Nakayama write about the determination of the excretory threshold of sugar. Sakaguchi, Gyötoku and Matsuyama discuss the variations in the excretory threshold of sugar. S. Yosida discusses the pharmacology of cobalt.

Band XXXII, Heft 2, contains an article by S. Idzymi on the biochemical and serological studies on hatched chicken eggs. M. Nakamura discusses the hemolysins in the colostrum of women. K. Takagi discusses the significance and the measurement of the röntgenologic shadow of the sella turcica and the shadows appearing in its vicinity. T. Sannai writes about dermoid cysts of the ovary.

Band XXXI, Heft 2, includes studies on neurotoxins by M. Ohta, an article on orthotic albuminuria by H. Hyeda, and the report of a case of myeloid chloroleucemia by Y. Harada and J. Nagai.

In Band XXXI, Heft 3, Y. Harada discusses the effective mechanism of adrenalin and the fate of the same in the organism. K. Mabuchi contributes some morphological studies on the behavior of the nerves in the female sexual organs of man with special consideration of the changes in their behavior during pregnancy and menstruation and in advancing age; an appendix refers to the nerves in the umbilical cord and placenta.

THE VICIOUS CIRCLE

God's Stepchildren. By Sarah G. Millin. New York: Boni and Liveright, 1925.

Nature has its cycles, slow moving but inevitable, and by the aid of this book one realizes a little more keenly perhaps that human living is but a part of nature, under the same cyclic bondage.

What the Rev. Andrew Flood was in in his mission to Darkest Africa is bound up in what his children's children become—the mixed breed sprung from him pursues its rise and fall slowly and surely like the seasons.

The Rev. Andrew Flood goes into the wilderness armed with a dream. Despite the cloth it is a selfish dream. It is that he shall bring the brown brethren to Christianity, thereby winning success, esteem for himself. He cannot conceive of his own unimportance in the scheme of things. And when the girl whom he honors with an offer of marriage rejects him, he quite literally turns his back on the world and sulks. Vistas of the easiest way open constantly before him, each made palatable by the thought that thus he, *he* will be nearer to his people, better able to help them, more looked up to by them.

He marries a native woman and has two half breed children. The daughter, so nearly white, is taught by a nearby minister until she mates with a Kleinhans. Their son, again so nearly white must *be* white. That is her dream and it shatters soon upon the rocks of reality. He marries a halfcaste and their daughter is white—almost. There follow his rise, her marriage, her child, her downfall. And the present generation is represented by a white clergyman. He marries an English girl with his mixed ancestry a secret from her. Their child—the mysteries of heredity remain unelucidated. But at last in this great, great grandson of Andrew Flood the native flair for reality breaks through. He throws aside the dream the generations have heaped upon him. He turns to the only thing that he can do, the completion of his forbear's task. The cycle is ended —where it began. Only thus can the unproductivity of the first man's life be rectified through knowledge —through unselfish service.

The author has given us a stifling human document. We feel that she has caught the pulse of living, that she has brought a different, more helpful understanding to a sociological problem than anyone else. She tells you about real people without romancing, without glory—each generation simply making the best of its blind course from birth to death.

Medicoliterary Notes.

A recent statistical report states that the Jewish farm population has increased from two hundred families to seventy-five thousand persons in the past quarter century.

* * *

The U. S. Bureau of Labor Statistics has added to its *Wages and Hours of Labor Series* bulletins on the subject as applied to the hosiery and underwear industry, 1907-1924; the paper and pulp industry, 1924; and in cotton, woolen and worsted goods manufacturing, 1924.

* * *

Among recent genealogical publications is a work entitled *The Descendants of Dr. James Hunter*, who came to Canada in 1822 from Yorkshire, England. Most of his descendants live now in the United States. Among the early

members were the well known English surgeon, Dr. John Hunter, and his brother, Dr. William Hunter. Frederick H. Hitchcock is the publisher. Another work of interest to the medical profession issued by the same publisher is the book entitled *Specialized Courts Dealing with Sex Delinquency;* a Study of the Procedure in Chicago, Boston, Philadelphia and New York, by George E. Worthington and Ruth Topping.

* * *

The milkman in Nome, Alaska, does not need to worry about spilling his milk. He calls from house to house and delivers a block of frozen reindeer milk or cream equal to a pint or a quart. A white cord frozen into the block of milk serves as a handle to facilitate delivering. The blocks of milk or cream are tastily wrapped in oiled paper looking for all the world like icecream.—*American Journal of Public Health.*

During 1924 it is estimated that 2,536 physicians died in the United States. Based on the estimate of 145,966 physicians in the United States, this is equivalent to an annual death rate of 17.37 as compared with 17.95 for 1923 and 16.94, the average for the last twenty-three years. The age of death of the 2,448 whose age was stated varied from twenty-two to ninety-nine years, the largest number of deaths at any given age occurring at sixty-five years. Of the 2,433 deaths for which causes were given, diseases of the circulatory system accounted for 893, the largest number. Diseases of the respiratory system caused 248 deaths, and of these 219 were due to pneumonia. Diseases of the genitourinary system caused 165 deaths, diseases of the digestive system 130, and diseases of the nervous system sixty-two. There were 102 deaths due to accidents, of which fifty-five were automobile accidents. Forty-five physicians ended their lives by suicide.—*Journal of the American Medical Association.*

Readers of the works of James Branch Cabell will be interested to know that in the book about Cabell by Carl Van Doren, recently published by McBride, is a map of that land of romance and mystery, Poictesme. Locations are shown of the places where many of the noble, and base, deeds of the Dom Manuel cycle were performed, including such thrilling spots as Storisende and Amneran Heath.

The issue for February of the *World's Health*, the monthly review of the League of Red Cross Societies published in Paris, contains two especially interesting biographical articles, one a sketch of the life and work of Gustave Moynier, who did more than perhaps any other one individual to establish the whole organization of the Red Cross; and the other an obituary notice of Professor Bergonié who died on January 2, 1925, a victim to his life work, the study of the x rays.

Professor Emory Holloway of Adelphi College has stated that a statue of Walt Whitman should be placed, most suitably, on the Battery overlooking Brooklyn ferry which he so greatly loved and celebrated in his poems. Professor Holloway feels that for the approaching foreigner to see the paternal hand of Whitman outstretched in welcome to the new world would make him feel much more at home than to view far above him the statue of Liberty, remote and perhaps a little supercilious.

How to Live, the bulletin of the Life Extension Institute for August, 1924, contains some interesting and alarming figures on automobile fatalities. In 1921 some of the causes of deaths in the registration area were as follows: influenza, 10,193; typhoid fever, 8,007; angina pectoris, 8,031; cirrhosis of the liver, 6,598; alcoholism, 1,611; *automobile accidents*, 10,168. This means that the automobile is more fatal than the typhoid bacillus, and kills many more people than does alcohol directly. The increase in the death rate from this source is even more alarming. In 1910-11 the death rate in 100,000 was 1.0; in 1911-15 it was 3.9; in 1916, 7.3; in 1917, 9; in 1918, 9.3; in 1919, 9.4; in 1920, 10.4; in 1921, 11.5; and in 1922, 12.5. The last figures show a rate twelve times that of 1900. The majority of accidents are attributed to carelessness, stupidity, self indulgence, and in some degree, to an exaggerated sense of self-importance on the part of many people. There are, the report states, only three good reasons for speeding—fire, accident, and illness.

Probably only a few of those who for many years have enjoyed the incomparable mystery and adventure stories of the late Rider Haggard know that, in addition to being a prolific writer, he was also greatly interested in social problems, particularly those of rural life in England. In 1901-02 he made an extensive survey of agricultural conditions in Great Britain, and was also a zealous worker in the social service activities of the Salvation Army. In 1912, he was knighted and among the services contributing to the receipt of this honor was the work he did as chairman of the Reclamation and Unemployed Labor Committee of the Royal Commission on Coast Erosion and Afforestation. He then traveled around the world as a member of the Dominions Royal Commission, and wrote four tales while he was voyaging. In 1917 he was made a member of the Empire Settlement Committee, and during and after the war worked unceasingly and zealously on the problems connected with emigration.

The bells of Carlisle Cathedral, England, which have not sounded since Prince Edward Charles Stuart crossed the border with his Highlanders 180 years ago, are to sound again. They have been entrusted to a bell founder to be cleaned, tuned and refitted. After the entrance of the Stuart prince into Carlisle in 1745, the bells were sentenced to one hundred years of silence. By the expiration of the period they were in such a state of repair as to make ringing impossible. The oldest of the bells was cast in 1410.—*New York Evening Post.*

Scented decoys for the deadly tsetse fly are now employed in upcountry districts by government entomologists. In order to trap and destroy the insects dummy animals are erected upon which the flies light and linger until they can be killed.—*Science.*

Abstracts from Current Literature

GASTROENTEROLOGY

Clinical Significance of Diverticula of the Duodenum.—Martin Haudek (*Wiener klinische Wochenschrift,* August 7, 1924) reports a case, in which a duodenal diverticulum in association with stasis in the stomach and duodenum gave a disease picture resembling ileus and resulted in death, lending support to the view that is frequently expressed in the literature, that duodenal diverticula may give rise to all sorts of dangers to the patient. On the other hand, the surgical removal of the diverticulum may cause many difficulties because the finding of the diverticula is not always possible. There is no clinical disease picture that is characteristic of duodenal diverticulum. Up to the present time it has never been possible to relieve the abdominal symptom complex by extirpation of the diverticulum, which occasioned the operation. Our previous experiences regarding the pathognomonic dignity of the duodenal diverticulum which occurs in three per cent. of all adults, are by no means sufficient.

Nonperforating Ulcers of the Stomach and Duodenum.—J. Emmons Briggs (*Boston Medical and Surgical Journal,* December 11, 1924) enunciates the following conclusions:

Carious and defective teeth are probably responsible for infections of the alimentary tract, gastric and duodenal ulcer, cholecystitis and appendicitis; hence the frequent association of these diseases. The most constant symptoms of ulcer are in the order mentioned: epigastric pain, loss of weight, vomiting, pyrosis, hemorrhage. History and x ray are the most important factors in diagnosis. Duodenal ulcers are twice as frequent as gastric ulcers. Gastroenterostomy with excision of ulcer is the ideal operation for gastric ulcer. Destruction of the duodenal ulcer (with gastroenterostomy) is desirable in order to assure a radical cure, and should always be done if bleeding has occurred. Massive hemorrhage should be treated medically until hemorrhage ceases and patient recuperates sufficiently to permit of resection of ulcer. Desperate cases of starvation from stenosis should be treated by preliminary jejunostomy. Acute ulcer should be treated medically: chronic indurating ulcer, surgically. Early postoperative vomiting signifies dilatation of the stomach, which should be treated by gastric lavage. Protracted postoperative vomiting, not relieved by gastric lavage, demands prompt surgical intervention and the most frequent cause is intestinal obstruction. Intestinal adhesions from previous operations may seriously complicate an otherwise well indicated gastroenterostomy for gastric or duodenal ulcer. No operations for ulcer should be made without inspection of gallbladder and appendix and, if diseased, these organs should be removed, if compatible with safety. A systematic followup system is the only way to obtain accurate knowledge concerning end results.

Attenuated Form of Pancreatitis.—Pierre Delbet (*Bulletin de l'Académie de médecine,* May 27, 1924) maintains that this is a rather common condition, which may be readily recognized on the basis of a certain symptom group, comprising chiefly pain and abnormal pulsations in the epigastrium. The pain is often diffuse and imperfectly localized by the patient. It may extend to the right or left of the midline. Pressure increases it, and sometimes compression of the lumbar fossa elicits more distress than that of the epigastrium. In the mildest cases the pain is relatively light, but the patients are nevertheless anxious to be relieved of it, and are sometimes looked upon as psychopaths. Where the pain is more pronounced, it increases toward the end of gastric digestion and is attended with a feeling of fulness and puffiness. Sometimes there are added attacks of severe pain suggesting hepatic colic or gastric ulcer. These patients are easy to examine, as there is little or no rigidity. No mass is felt, but the pulsations of the aorta are at once perceived. In their subjects the abdominal wall is pushed up at each systole. The pulsations are seen transversally over a distance much greater than the diameter of the vessel. Often there is anorexia, slight loss of weight, and digestive disturbances presenting no special characteristics. The pulsations are not expansive, and are therefore not due to aneurysm. Their abnormal extent is ascribed to the presence of thickened, indurated tissues between the vessel and the parietes. That the pancreas is the organ concerned is believed shown by a case in which the symptoms already described were followed, after a time, by a more rapid progress of the disease, with jaundice and the appearance of a large mass between the ensiform and the umbilicus, elevated by the aortic pulsations. Operation revealed a pseudocyst of the pancreas, and as soon as the pressure was relieved the jaundice disappeared. Attenuated forms of pancreatitis may either be completely recovered from, lead to fibrosis of the pancreas with pressure on the biliary tract, or result eventually in a pseudocyst of the pancreas. The cause of attenuated pancreatitis appears to be the same as in the typical acute pancreatitis.

Duodenectomy.—C. A. Pannett (*British Journal of Surgery,* October, 1924) offers a small series of cases in which the mortality rate was low, with a view to popularizing the operation of duodenectomy employed throughout his series. He gives the operative technic in full, emphasizing in particular two pathological facts which assume great prominence in duodenectomy, namely, the tendency to widespread fibrosis in the neighborhood of the ulcer, and the frequency with which two ulcers are present. The first phenomenon is so important because of the nearness of the common bile and pancreatic ducts and their liability to injury unless great care be taken, for they early become surrounded by fibrous tissue which has invaded the gastrohepatic ligament and pancreas. In the case of the stomach it is easy to control the blood supply before resecting, by ligature of the main vascular trunks. But this is not possible in the case of the duodenum, because the pancreaticoduodenal artery conveys blood, not only to the duodenum itself, but to the head of the pancreas. It is therefore necessary to ligate the numerous small branches which come off from the vessel and enter the pancreatic wall of the duodenum. This is a tedious and timeconsuming procedure, but it must be done with meticulous care, since the obscuration of the area of operation by blood may lead to serious consequences from loss of the power of orientation. There are indeed two main guiding principles in duodenal resection: to keep the dissection close to the wall of the viscus, so that damage to the bile or pancreatic ducts may be avoided; to control the blood supply by tying the small terminal branches separately.

Cholecystogastrostomy and Cholecystoduodenostomy.—F. G. DuBose (*Surgery, Gynecology and Obstetrics,* September, 1924) complains of the unsatisfactory end result in gallbladder surgery and offers the following indications and contraindications for cholecystenterostomy as the operation of choice.

Contraindications.—1, cancer or other gallbladder neoplasms; 2, gangrenous cholecystitis; 3, atrophic or contracted gallbladder, and 4, cystic duct occlusion or obstruction other than stone.

Indications.—1. Common duct obstruction in patients who are poor surgical risks from extreme illness, complications or associated physical diseases. When safety first is regarded, cholecystenterostomy is the best remedial measure available. 2. Residual hepatic duct stones when secondary common duct obstruction is a probability. In these cases cholecystectomy is contraindicated, and also cholecystostomy because a continuous and perhaps complete external flow of bile may result. 3. Chronic or intermittent jaundice of obscure origin; or jaundice secondary to inoperable disease of the liver, pancreas, or duodenum, causing obstruction to the common duct. 4. Perforation of the gallbladder. Cholecystenterostomy is safer than cholecystectomy and gives a more rapid convalescence than cholecystostomy. 5. External drainage consequent to operations on the upper abdomen after the removal of gall stones. Anastomosis is safer and simpler. 6. Perforation of a pyloric or duodenal ulcer. The chance is lessened of constricting the lumen and promoting healing of the ulcer area by bathing it continuously with the alkaline bile. 7. Persistent pyloric spasm from hyperacidity unrelieved by medical treatment. 8. Acute pancreatitis. Cholecystenterostomy permits of free drainage of bile, yet conserves it for the patient's use, and is to be preferred to either cholecystostomy or cholecystectomy.

Therapeutic Enterostomy.—M. F. Porter (*Annals of Surgery,* October, 1924) believes that enterostomy in an obstructed loop of intestine prior to removing the cause of obstruction will frequently aid in determining whether or not excision is necessary, will lessen the danger of fatal toxemia following relief of obstruction, and make the relief of the obstruction easier, whether or not there is strangulation. Many of the deaths following operation for bowel obstruction might be prevented by opening and draining the obstructed bowel of its contents before the obstruction is removed. The danger from soiling the wound may be avoided in large measure and is not as great as is the danger from absorption of long obstructed bowel content. The danger and inconvenience of enterostomy have been exaggerated; while the benefits to be derived therefrom have been underestimated and a correct valuation with consequent modification in surgical procedure would be beneficial.

Rupture of Intestine with Strangulated Hernia.—F. LeM. Hupp (*Annals of Surgery,* October, 1924) points out that in dealing with a strangulated hernia, with death of the bowel, there are at least two mortality factors to be considered in addition to the shock occasioned by the intestinal block:

First, the possibility of an intraabdominal leak, due to a partial or a complete rupture at the point of the constriction from pressure necrosis.

Second, there may be further added a definite pathological entity in the form of an ulceration of the gut, leading to a postoperative perforation. That this accident has been recorded with increasing frequency, and this fact should lead to a searching interrogation of the mucous membrane immediately adjacent to or beyond the line of anastomosis, in order to forestall a potential leakage.

Experimental Pancreatectomy.—Hédon (*Presse médicale,* March 7, 1925) relates that a completely pancreatectomized dog was kept in excellent health and at normal weight for fourteen months by means of two daily injections of insulin, which checked his diabetic tendency, and ingestion of pancreatic ferments, which controlled his digestive disturbances. All functions remained normal, including the sexual function. Complete interruption of the insulin treatment brought on intense glycosuria and the appearance, on the sixth day, of evidences of grave acidosis. In addition to sugar, the urine showed albumin, hemoglobin, bile pigments, casts and fat. Resumption of insulin overcame the glycosuria, but in no wise improved the general condition. On the seventh day, in profound coma, the animal was moribund, his alkali reserve having fallen to eleven in 100. Three intravenous injections of sodium bicarbonate, totalling five grams, revived him in a marvelous manner. On the next day, he was strikingly improved, and large amounts of insulin and carbohydrates completed his restoration in a few days. Prolonged administration of insulin in this animal is not thought to have exerted the least toxic effect on the internal organs, otherwise prompt and perfect recovery from so serious a condition could not have occurred.

Improved Technic for Intestinal Anastomosis.—C. A. Roeder (*Annals of Surgery,* December, 1924) offers an operative technic whose desirable features are its ease and rapidity of application, its relatively high degree of asepsis and its resulting large lumen, due to a very narrow rim of intestinal tissue remaining within. The intestine is crushed three to four eighths of an inch wide, on an angle of about fifty degrees. A long narrow bladed clamp is applied in the crushed area adjacent to the segment to be resected and another similar clamp placed closely parallel with it; which leaves, for a later step, fully one fourth of an inch of crushed intestine proximal to the remaining clamp. The intestine is then amputated with a cautery, and the clamps remaining on the segments to be united are brought closely together. One continuous mattress suture of fine linen is then passed through both segments, along the edge of the crushed tissue, where it adjoins the normal intestine. This linen approximating suture becomes slightly contaminated as it passes through the crushed intestine, but is easily sterilized with a swab of pure phenol. This is the only step of any danger and can be safeguarded by simple isolation with packs, and the use of phenol on the suture. We now have the ends of the segments to be anastomosed closely approximated by the single temporary linen suture held taut between two forceps; and distal to the suture we have superfluous crushed tissue which is again amputated with a cautery to within about an eighth of an inch from the linen suture line. This leaves a rim of crushed intestine only one eighth of an inch wide, which is inverted by a single layer of Lembert anastomosing suture of fine silk. The anastomosing suture, using the linen approximating suture as a pivot, must be very accurately and uniformly passed entirely around the approximated segments and through the very edge of the uncrushed intestine. I have found that if the suture is started on the side opposite to the approximated crushed edges, the procedure is greatly facilitated. After the anastomosis has been completed the temporary linen suture is cut and pulled through, leaving the crushed edges still obstructing the joined segments. The index finger and thumb then invert the intestinal walls through the rim of the Lembert suture, opening the anastomosis, which will be found to have a lumen amply sufficient. Soft clamps are occasionally applied on the intestine about three inches away from the resected ends in order to retain intestinal contents; however, this is generally unnecessary. The small intestine is frequently anastomosed, end to end, to the large intestine, and I have found that by increasing the length of the crushed area in the small intestine, the operation can be carried out in the same manner as above. Again in this operation the main point in technic is the suturing which must be planned to invert as little intestinal tissue as possible.

A Statistical Study of Eight Hundred and Eighty-Eight Cases of Biliary Tract Disease.—Alfred Blalock (*Bulletin of the Johns Hopkins Hospital,* December, 1924) divided the cases into two groups, depending on the presence or absence of stones, and their position when present. This interesting and somewhat lengthy statistical study includes a consideration of the etiology, symptoms, physical findings, laboratory findings, operations and reoperations, bacteriological and pathological findings, and the course immediately after operation, and ultimate results. A few of the more important points brought out in the cases of disease of the biliary tract treated surgically are the following: The average age was forty-four, the highest incidence being in the fifth decade. The most common symptom was pain. Jaundice was present in thirty-nine per cent. of all cases, the highest percentage being in the group with stones in the common duct. The leucocyte counts were surprisingly low, in few cases over 15,000. X ray studies showed stones in thirteen per cent. of the cases in which plates were made. Fifty-eight per cent. of all cultures taken at operation were positive, the predominating organism being Bacillus coli, and Bacillus typhosus ranking next. The stay in the hospital was usually shorter and less disagreeable after cholecystectomy than after drainage of the gallbladder. The percentage of cured and improved patients following cholecystectomy and cholecystostomy was about the same but only thirty-nine per cent. of the deaths followed cholecystectomy, and sixty-one per cent. followed drainage of the gallbladder. The facts presented lead the authors to conclude that the gallbladder should be removed in all cases in which it is disease, whether stones are or are not present, except in cases with malignancy of the biliary tract, provided that the condition of the patient is such that the added time under anesthesia will not lessen too greatly his chances for recovery. In malignancy of the gallbladder, when a positive diagnosis can be made without exploration, no operation should be performed, inasmuch as it only shortens the patient's life.

Studies on the Total Bile.—Douglas R. Drury (*Journal of Experimental Medicine,* December, 1924) investigated conditions influencing the calcium content of the bile, making a day to day study of the calcium content of the total liver bile of dogs intubated under sterile conditions. The concentration of calcium in the bile was found to be fairly constant under physiological conditions not involving wide fluctuations in the secretory output. The calcium yield for each twenty-four hour period varies in general directly with the amount of bile. When this amount becomes greatly lessened, as the result of fasting, the concentration of calcium becomes markedly increased, though not sufficiently so to compensate for the lessened volume. When the bile is much above the average, after the ingestion of food in quantity, the calcium content, unlike that of pigment, does not become correspondingly diminished, but tends to remain the same as usual. So when great amounts of bile are put out,

so too are relatively great amounts of calcium. This is not caused by the increased ingestion of the element, for neither feedings with bone meal, nor the administration of large quantities of calcium salts intravenously or by mouth have any effect on the biliary output of calcium. The normal gallbladder, far from secreting calcium into the bile, as some have thought, acts to remove this element from the secretion, and removes carbon dioxide as well. The "white bile," which is a specific secretion of the bile ducts, contains but little calcium, like the mucous secretions from elsewhere in the body. The concentration is only slightly greater than that in the blood plasma, and contrasts significantly with the high concentration to be noted in true bile of the fasting animal. Evidently the greater portion of the bile calcium must be secreted, not by the duct walls, but by the liver itself. The findings have an evident bearing on the problem of cholelithiasis.

Jaundice.—J. W. McNee (*British Medical Journal,* September 20, 1924) states that the most recent theory of jaundice is based upon the claim that the cells of the reticuloendothelial system, particularly of the spleen, which elaborate the bile pigment, and that the polygonal cells of the liver, are mainly concerned with its passage into the bile. The direct and indirect Van den Bergh reactions serve to explain the two varieties of bilirubin and it is possible that the bilirubin in passing through the glandular liver cells is modified in some way. The following classification of jaundice is proposed: Obstructive hepatic jaundice, toxic and infective hepatic jaundice, and hemolytic jaundice, which include all the clinical varieties of jaundice. Some of the clinical types may have to be placed in two of these divisions.

Leucocyte Counts in Acute Appendicitis.—W. C. Menninger and H. S. Heim (*Annals of Surgery,* December, 1924) present a detailed study of the relationship between the total leucocyte count and the percentage of polymorphonuclear leucocytes, with special reference to the effect upon this relationship of sex, age, temperature, pathological process and infecting organism. They find that the total leucocyte count is a measure of body resistance against an inflammatory process up to a certain degree of leucocytosis; the percentage of polymorphonuclears is an index of the severity of the inflammatory process; and that the greatest aid to be obtained from a preoperative blood count as to indication for operation, is the relationship of these two, as described in this article. Females show a slightly better resistance than males, but the difference is so slight, that we do not give it weight. The younger the patient, the better is his resistance. This fact, which is generally regarded as an axiom, is here supported by actual findings, and has been found to hold for all ages. The temperature, as shown in a series of cases, is proportional to the polynucleosis and to the resistance index, although it shows slight variation under 101°. The best resistance is offered by the individual against the less severe pathological process. With an extensive process, the body resistance is overwhelmed. The type of organism very probably plays a rôle in the severity of the inflammatory process and consequently in the resistance index, but because of varying degrees of virulence of different strains of the same organism, definite conclusions can not be drawn from the data here presented.

Primary Carcinoma of the Appendix.—Howard A. McCordock (*Buffalo General Hospital Bulletin,* July, 1924) reports three cases of socalled carcinoma of the appendix. Two of these cases were typical carcinoids while the third case was apparently a double carcinoma, a carcinoid and a gelatinous (colloid) carcinoma, the former involving the distal, the latter the proximal part of the appendix where a rupture occurred leading to escape of gelatinous material (pseudomucin) into the peritoneal cavity. In the literature the vast majority of reported cases of primary carcinoma of the appendix belong to the carcinoid type and only one of these is known to have developed malignant qualities. The rest of the reported malignant primary carcinomas of the appendix were probably such as might occur in any part of the intestinal tract. Some observers regard the carcinoid type of tumor as a carcinoma with a limited degree of malignancy, while others as tissue malformations. A socalled mucocele of the appendix, studied in conjunction with the author's gelatinous carcinoma, appeared to resemble the latter in structure, and the question is raised whether many of the reported mucoceles were not really similar tumors. The author's gelatinous carcinoma developed from the carcinoid although the morphological proof of transition from one into the other is not very strong. Assuming the solid carcinoid to be a tissue malformation with glandular potency, it may by progressive growth and development be converted into a glandular tumor and finally be subject to mucoid degeneration yielding the type of growth known as gelatinous carcinoma. Such metamorphoses would not necessarily lend the growth any malignant characters, which would be in harmony with the lack of malignancy of many of the reported cases of glandular carcinoma.

Early Diagnosis of Carcinoma of the Stomach.—E. Schütz (*Wiener klinische Wochenschrift,* August 7, 1924) draws the conclusion that the diagnosis of carcinoma of the stomach is justified even in the absence of other objective signs in the presence of anacidity associated with an abundant bacterial flora in the gastric contents (long or short bacilli) and that the finding of coincident symptoms of a pyloric stenosis makes the diagnosis of an early stage of this disease possible. This finding also has another practical bearing, namely, that in such cases one should not be satisfied merely was a gastroanastomosis, but the radical operation should be done wherever possible. Whether the outlook for a permanent cure is more favorable than in the more advanced disease, only the future can tell.

Lymphosarcoma of Small Intestines.—F. W. Rankin (*Annals of Surgery,* November, 1924) finds that treatment by whatever methods undertaken usually yields unsatisfactory results. If the diagnosis be established before too much lymphatic invasion has taken place, surgery seems to offer the best chance of cure or at least the most palliation. Where the process is extensive and where a resection would involve the sacrifice of too wide an area of bowel substance palliative measures such as sidetracking operations are indicated. Radium in certain sarcomatous cases has given such excellent results that some observers have been stimulated to urge its use in this condition. Certainly the end results from surgery are poor, even from the viewpoint of prolongation of life, to urge it as other than a last resort. Under any of the present day treatments the prognosis is poor, and unless the early diagnosis of this condition can be made there is relatively little chance of instituting other than palliative measures. It is suggested that radiological evidence may be of greater value in an early diagnosis of these lesions under a more improved technic than we have at present. The insidiousness of the disease and its lack of a consistent symptom complex seem to show conclusively that we must look to the röntgenologist for progress in making an earlier diagnosis, if we are to reduce the mortality by any therapeusis now available.

CARDIOVASCULAR DISORDERS

Action of Quinidine in the Treatment of Heart Disease.—John Hay (*Lancet,* September 13, 1924) cites the following types of cases in which it is admittedly unwise to administer quinidine:

1. It is more than probable that little or nothing is to be gained from quinidine in badly damaged hearts with valvular disease of long standing, and more particularly if there is undoubted failure of compensation with venous engorgement. Here digitalis is the best drug to administer in the attempt to control the ventricular rate and improve the reserve power of the heart. 2. Occasionally, in a patient who has suffered severely from angina pectoris, the onset of fibrillation is followed by the cessation of the anginal pain, and it is a question whether one should attempt to restore a normal rhythm under these conditions. 3. Idiosyncrasy. Rarely the patient is unduly sensitive to quinidine, and to push the drug induces unpleasant or even dangerous consequences. 4. All cases of acute or subacute infective endocarditis. 5. A history of embolism would be a factor against the administration of quinidine.

The cases suitable for quinidine treatment are the following: Quinidine is most likely to be of service when the fibrillation is of recent development, and when there is but little cardiac enlargement and no valvular disease; as, for example, a case of paroxysmal fibrillation with the last paroxysm persisting. Another favorable type of case is that of a patient in whom the onset of fibrillation was due to, or at least associated with, an acute infection, such as influenza or the presence of an infective focus. When the onset of distress definitely dates from the incep-

ion of fibrillation, and it is clear that the abnormal rhythm s the disabling factor, then the advisability of adminis- ering quinidine should be favorably considered. Quinidine las proved of great value in the fibrillation associated vith exophthalmic goitre, especially where partial thyroid- ctomy has been performed and the fibrillation persists. Quinidine is also valuable before operation in the milder ases of exophthalmic goitre in which fibrillation is present. Each case must be considered on its own merits. There re no hard and fast rules. Often the results are far etter and more permanent than was to be expected— nore frequently, however, they are disappointing. Either he fibrillation persists or the recovery is only temporary. When it is permanent most patients are conscious of some hange for the better. The symptoms are ameliorated nd the cardiac reserve is increased. In favorable cases normal mode of life is resumed. Quinidine is given vith the hope that it will restore a normal rhythm, but he result is sometimes disappointing.

Action of Tartar Emetic on the Heart.—William D. Reid (*Boston Medical and Surgical Journal,* December 18, 924) has studied the action of tartar emetic, which ormerly was popular as a circulatory sedative, by means f the electrocardiograph in a small group of clinically ormal hearts, and in others affected by auricular fibrilla- ion and ventricular extrasystoles. The most noteworthy indings were: Reduction in the heart rate, prolongation f the P-R interval, increase in the height of the T wave, nd slowing of the rate of the circulating wave in auricular ibrillation.

Adrenalin Treatment of Stokes-Adams Attacks.—John Parkinson and C. W. Curtis Bain (*Lancet,* August 16, 924) recall that whatever the block, it is only where he attacks depend upon strong vagal influence—a rare vent—that the commonly used subcutaneous injection of tropin might be expected to succeed. Clinical experience onfirms this and shows that it is most uncommon for tropin to control the attacks. On pharmacological grounds drenalin might be expected to have a wider application han atropine in the treatment of Stokes-Adams attacks. t can facilitate conduction when partial block is present. What is more important is that it can directly increase he rate of a dissociated ventricle. Further, it has been linically shown, even if the block is uninfluenced and he ventricular rate is not increased, adrenalin can abolish he recurrent standstill of the ventricle which under these onditions determines the syncope. The authors believe hat the subcutaneous injection of adrenalin, using five o ten minims of the 1 to 1000 solution, is the most romising method of treating Stokes-Adams attacks.

Stair Climbing as a Test of Cardiac Function.—J. H. Wallace (*American Journal of Diseases of Children,* Sep- ember, 1924) used the following test: The work consisted f a rapid climb (a trot) up forty steps, an elevation of wenty-three feet, from the ground to the third floor. This ncluded walking on the level of about twenty feet and naking five turns. It was usually accomplished in about wenty-three seconds. For a five minute interval prior to he climb the patient was seated at the foot of the stairs, hen the blood pressure and pulse rate recorded. Immediately ollowing the climb the patient was again seated at the top f the stairs and the blood pressure and pulse rate read very thirty seconds for a period of six minutes.

The children recommended, on the basis of history and hysical examination, as having chronic heart disease with lightly diminished exercise tolerance, performed the activi- ies of normal childhood easily and without evident physical letriment. Rather strenuous stair climbing was performed y this group easily and without evidence of cardiac em- arrassment. A study of the blood pressure reaction changes after a given piece of work reveals that in children with mild heart disease the reaction time is usually longer than in children with normal hearts, and that it is longer still in children with more severely damaged hearts.

The blood pressure and pulse rate reaction times follow- ing a given work test were recorded before the beginning of a period of supervised rest, play and work and again from three to four weeks later. Although the subjects showed obvious general improvement, a comparison of the two sets of reaction periods showed a tendency toward increasing, rather than decreasing, blood pressure and pulse rate reaction periods.

A Heretofore Neglected Form of Respiratory Disturbance in Angina Pectoris (Aortic Dyspnea).—Sigmund Wassermann (*Wiener klinische Wochenscrift,* September 11, 1924) describes a peculiar form of respiratory disturbance occurring in attacks of angina pectoris, which may be recognized by the following characteristics:

1. It occurs simultaneously with the anginal attack or introduces it (as a premonitory sign) and runs its course along with the attack. As the anginal attack is relieved, the dyspnea also disappears.

2. It is associated with the sensation of difficult breathing (dyspnea), of constriction (oppression) and of fear (angor). Frequently it is experienced as painful and oppressive (sternal or precordial pressure).

3. In cases with frequently recurring anginal attacks it appears as a stenocardial equivalent and the purely painful stenocardial factors cannot be differentiated sharply enough in the dyspneic "attacks." The identification of these stenocardial dyspneic equivalents is made possible by the prominence of formerly typical anginal attacks.

Adynamia and Hypodynamia of Muscle and Their Therapeutic Problems.—J. Pal (*Wiener klinische Wochenscrift,* May 29, 1924) states that digitalis can aid the functional ability of the heart through stimulation of the kinetic elements of the pathological heart, provided the new formation of energy substance is possible. In cases of cardiac weakness that is of tonic origin, more is to be expected from caffeine and less from digitalis. In the presence of a normal frequency caffeine alone is preferable owing to its advantages for the coronary bloodvessels, the bronchi, and the pulmonary circulation.

For the purpose of building up the tonus, nutritive substances, of which the infusion of dextrose was found best by the author, are necessary. The author's investigations have shown that the shorter the duration of the process, the greater was the effect, because the structure of the muscle fibre was still sufficient. The building up of the tonus of the other hollow viscera is still a moot question. The adynamias of voluntary muscle of neurogenic origin present the simplest problem. The reconstruction may be accomplished through the physiological stimulation as soon as the etiological process has returned to normal. On the whole, the conclusion may be drawn that the result of treatment is dependent not only upon the choice of the remedy but also upon the existing structural condition of the cells, and this presents the greatest difficulties.

Cervical Sympathectomy in Angina Pectoris.—William H. Holmes and S. W. Ranson (*Journal of Laboratory and Clinical Medicine,* December, 1924) describe the case of a white woman fifty-three years old, in whom the paroxysmal pain of angina pectoris was relieved by the removal of the superior sympathetic ganglion. She has remained under observation for eleven and a half months without a single recurrence of thoracic or brachial pain of the anginal type. The beneficial effect of high cervical sympathectomy in attributed to section of the vasoconstrictor fibres by the authors, instead of to section of sensory fibres, as is done by Coffey and Brown. The authors state that the idea that the paroxysms of angina pectoris are due to structural change plus vascular spasm has long held a prominent place among the theories advanced in explanation of the symptoms of the disease. Not being able to account for the results obtained by section of the superior cardiac nerve on the basis that it contains sensory pathways, the hypothesis is advanced that this nerve contains vasoconstrictor fibres for the aorta and coronary arteries, and that section prevents spasmodic vasoconstriction and, therefore, stops paroxysmal pain, but is without effect on pain caused entirely by structural changes.

Massage of Heart in Cardiac Arrest.—W. E. Lee and T. McK. Downs (*Annals of Surgery,* October, 1924) report on several cases, concluding that the earlier cardiac massage is instituted after cessation of the heart beat, the greater is the likelihood of success. Time should not be lost waiting for hypodermic stimulation to act. If the circulation has actually stopped, it cannot act. The quickest and the easiest method of approach is the best. This is usually the abdominal transdiaphragmatic route. If this is not successful within two or three minutes, the diaphragm should be incised, the heart grasped in the hand and directly stimulated. No patient should be abandoned until cardiac massage has been tried without success.

Aneurysm of Palmar Arches.—H. H. M. Lyle (*Annals of Surgery,* September, 1924) offers the following conclusions to a tabulated series of cases: Aneurysms of the superficial palmar arch are not common, aneurysms of the deep palmar are extremely rare, only eight having been recorded. The majority of the cases are caused by trauma with direct injury to the vessel wall, an insignificant number result from local or general pathological disease of the vessel wall, a small group are caused by chronic irritation and repeated contusions. The best treatment is an early excision of the aneurysm; this applies to both the superficial and deep arches. As a prophylactic measure, all narrow penetrating wounds which bleed freely and are in possible relation to the palmar arches, should be explored and both ends of the artery secured. Although these aneurysms do not occur frequently, we should remember their possibility and in the prognosis of a trauma to the palm reserve a place for them.

Aneurysms of the Iliac and Femoral Arteries.—J. E. Thompson (*Annals of Surgery,* June, 1924) traces the circulatory routes through the various arteries with a view to explaining the complications consequent upon operation of this disease. The most effective operative treatment for an aneurysm arising from the external iliac and encroaching on the bifurcation of the common is to tie both common and internal iliac arteries simultaneously. The intrasaccular suture of Matas is less likely to be followed by complications than any other method of treatment, first, because evacuation of the clots from the sac relieves the surrounding tissues from pressure. This allows the collateral arteries to open up to their full capacity and often relieves impending gangrene. It also allows the companion veins to expand and edema is similarly relieved. Both these results are seen with surprising rapidity after evacuation of the clots from a popliteal aneurysm. Secondly, the suture of the arteries opening into the sac is done from within, consequently the walls of the sac are not disturbed, and collateral channels cannot possibly be injured. Further, any vital trunk, such as the profunda femoris or internal iliac, is closed by suture at its mouth, and the arterial stem and its branches are not endangered.

Arteriovenous Aneurysm.—E. Holman (*Annals of Surgery,* December, 1924) finds that clinically the circulatory changes following the introduction of an arteriovenous fistula are dependent primarily upon the size of the fistula and upon an unobstructed return flow to the heart. Small fistulas, however long they may have existed, do not cause changes in either vessels or heart. Slightly larger fistulas may result in an enlargement of the proximal vein, but no visible change in the heart or proximal artery. Large fistulas are inevitably accompanied by changes in both artery and vein and usually by a demonstrable enlargement of the heart. The extent of these changes is intimately dependent upon the size of the fistula. These clinical observations are identical with those found in the experimental laboratory and are undoubtedly dependent entirely upon the amount of blood which finds its way through the fistula back to the heart.

Pathology and Surgical Treatment of Angina Pectoris.—Daniélopolu (*British Medical Journal,* September 27, 1924) suggests that in angina pectoris there should be cut the cervical sympathetic cord, and the vertebral nerve above the inferior cervical ganglion, the nerve of Hofer, or any corresponding nerves present, and the nerves which spring from the cervical sympathetic cord above the superior cervical ganglion and pass to the heart. Thus, while preserving the important centrifugal nerves which are essential to the action of the heart, we are cutting the greater number of ascending sensory fibres to which is assigned an important part in the launching of the anginal attack. Only by this operation as detailed above can permanent benefit be obtained. The lateral sensory group which enters the thoracic cord is certainly left intact, but this group is only of secondary importance. Since the principal site of the anginal attack is the left side of the heart, and it is the sensory nerves of the left side which are mainly affected, the operation must be performed on the left side in the first place. Is it necessary to complete it on the left side? It would be difficult to give any categorical answer, but it is more than likely that in the majority of cases the operation on the left side would be sufficient.

None of the surgical methods suggested can yet be considered the ideal; it is certain that cervicothoracic sympathectomy must be absolutely abandoned, while each of the other methods has as yet done no more than establish a right to be considered in therapeutics. In the present state of our knowledge regarding the innervation of the heart and aorta in man it is only possible to outline a hypothesis, but research is proceeding.

Aneurysm of the Splenic Artery.—E. A. Baumgartner and W. S. Thomas (*Surgery, Gynecology and Obstetrics* October, 1924) present a tabulated series of forty cases thirty-three of which were diagnosed at autopsy. With reference to the diagnosis they conclude that with the symptoms of abdominal pain, gastrointestinal hemorrhages splenic and epigastric tumors, and x ray studies ruling out tumor of the stomach, aneurysm of the splenic artery should be considered and operation advised, for in operation lies the only hope of recovery in these cases.

Aneurysm of Internal Mammary Artery.—F. W. Rankin (*Annals of Surgery,* September, 1924) gives several differential diagnostic signs between aortic and internal mammary aneurysm, and says, of the treatment, that the rich anastomosis between the intercostals and phrenics below suggests the impossibility of cure without radical extirpation of the sac. The resection of a portion of the chest wall and the costal cartilage following a preliminary ligation of the vessel in the first or second interspace and also below the aneurysm, with a total extirpation of the sac, is a feasible procedure which may be carried out without injury to the pleura or danger of unpleasant sequelæ.

A Cardiac Index for Children.—J. Epstein (*Archives of Pediatrics,* September, 1924) states that a large number of valuable experiments by means of dumb bells, iron bars and the ergometer have led to the following conclusions:

A moderate amount of work will cause no change in the systolic blood pressure in normal children. With an increased amount of work, there will be a systolic rise in blood pressure immediately after work, which quickly returns to the original level. When the work is increased to the point of fatigue, there will be a delay in the systolic rise and a slow return to the normal. But when a moderate amount of work produces a systolic delay, it is evidence of a functional cardiac insufficiency. An oscillation in blood pressure after a moderate amount of work, consisting of a primary fall followed by a rise and a return to normal means myocardial weakness. The systolic rise or delay cannot fully interpret the cardiac functional capacity, however, because the blood pressure in itself is a component of various factors.

Gradient efforts of moderate running, climbing stairways walking on level ground, and resting with a corresponding graded cardiac index of 1.0, 0.75, 0.5 and 0.25 will serve as a reliable and useful guide to the cardiac vital capacity. These exercise tolerance tests require no special instruments, do not exhaust the patient and do not throw out of gear other systems and organs of the body. In the young child it can easily be estimated by the subjective and objective reactions while an older child can fully express his cardiac responses to these daily tasks imposed upon it. They are easily applied and are drawn from the child's daily exertions.

A child with a cardiac index of 1.0 requires no treatment except graduated exercises to strengthen his cardiac reserve. One with a cardiac index of 0.75 needs occasional medication and careful exercise. An index of 0.5 calls for a great deal of rest and digitalis. When the index is only 0.25 the little patient must be completely at rest and digitalized.

The cardiax index is determined as follows: When, in spite of some mechanical valvular impediment, the child can perform all the types of exercise without drawing on his cardiac reserve and experiencing shortness of breath, fatigue or other evidence of heart weariness, his cardiac index is 1.0 (100 per cent.). If he cannot do moderate running without dyspnea or other cardiorespiratory distress and is only able to climb the usual number of stairways, the index is 0.75. If the child can neither do moderate running nor walking up stairways without overloading the heart, and can walk only on level ground, the index is 0.5. When the cardiac reserve is so far exhausted that the child is unable to run, climb stairs, or even walk on level ground and is comfortable only when at rest, the cardiac index is 0.25. Failure of compensation even at rest means cardiac dissolution.

PEDIATRICS

Diphtheria Immunity.—W. H. Park and Abraham ingher (*American Journal of Diseases of Children,* October, 1924) draw the following conclusions from a study of ıe immunity results obtained with diphtheria toxoid (modified toxin) and one tenth L+mixtures of toxin-antitoxin in ıe public schools of New York City.

1. Both the new toxin-antitoxin and the toxoid preparations give good immunizing results with but slight local ıd constitutional reactions.

2. The toxoid has advantages in that there is no horse rum in it to cause sensitization, which happens to a slight egree with toxin-antitoxin. The substitution of goat antioxin for horse antitoxin will obviate this difficulty and ıis change is now being made.

3. Such a toxoid would do away with the fear in the popuıtion created by the recent experience with frozen toxinıtitoxin.

4. A satisfactory toxoid preparation is probably easier to ıake and also more stable.

5. In making toxoid by the addition of formaldehyde to oxin, care must be taken of the amount of formaldehyde ıded and the period of time the formaldehyde treated oxin is exposed to the temperature of the incubator. The mount of amino acid nitrogen, as determined by the van lyke method, has a definite bearing on the amount of ormaldehyde that is necessary to be added. Many of the oxin preparations containing from 2.5 to 5 mg. of nitrogen er 10 c. c. will require the addition of 0.1 per cent. ormaldehyde and the exposure in the incubator from four five weeks.

6. Careful tests of the minimum lethal dosage, the L+ ıd the flocculating value of the toxoid should be made in andardizing the preparation. The minimum lethal dosage epresents the remaining trace of free acting toxin, the L+ ıd the flocculating value, the combining power of the toxoid. he combining value of toxoid serves as a good index of s immunizing value. It is of advantage to have a slight xcess of free toxin (from 1/15 to 1/20 minimum lethal ose in each dose) in the toxoid.

7. Toxoid and toxin-antitoxin should be carefully studied ıd, if possible, improved, and the one that is shown to be ıe best adopted for general use.

Mongolism.—Thomas Brushfield (*British Journal of hildren's Diseases,* October-December, 1924) reports his ndings in a series of cases of mongolism. The etiology ıd pathogenesis are still obscure. The various factors beeved to be effective include syphilis, contraception, neuroıthic family history, an abnormally small and tight amnio c sac during intrauterine life, position in the family, and ıe mother's age and health in pregnancy. The clinical ıaracters are distinct. With the exception of the tongue, one alone is characteristic, and any single one may be ound in other varieties of amentia. In the order of their nportance they are: the brachycephalic skull, the small ounded "bullet head," having a high cephalic index; a attened and rounded face, the cheeks marked with irregular d blotches, fine hairs over the forehead, dry, coarse, often aly skin and a fairly high forehead with no recession. he palpebral fissures slope outward and upward. Epiınthus is common. Nystagmus is seldom seen, and then ry coarse movements are present. The iris may be ottled or marbled, or speckled. Vision is generally defecve, due to hypermetropic astigmatism. Cataract may be esent. More or less strabismus is present without exceon. Blepharitis and conjunctivitis may become obstinate ıd chronic. The tongue is often protruding, very large, ick and long; the circumvallate papillae become hyperophied; transverse, fissures appear and become more arked with advancing age. The mouth is generally open ıd the lips often show longitudinal fissures and cracks. entition is generally late and nearly always irregular; the eth are brittle and decay early. The dry mouth with fective salivary secretion favors the occurrence of caries. fter the sixth year there is nearly always alveolar hyperophy; it is narrow, high, often with a central, well develed ridge in the vertical plane; the sides often appear vertıl. The voice is gruff, low pitched, guttural. The ears e small, badly developed; all are simply convoluted, some ıellshaped. The nose is short, generally squat, nostrils oking forward and narrowed, with a markedly depressed idge, and an associated nasal catarrh. The nasopharyngeal cavity is small and shallow. The hair is generally light or medium brown in color, coarse, wiry in boys, often scanty and splitting; the skin of the scalp is scaly or scurfy. The skin is dry, harsh, thickened on feet and hands. Blue patches or spots may be found in the intergluteal fold and sacral regions, and are congenital. Lax ligaments are especially characteristic. The vulnerability of all mucous membranes is marked.

The hand is very variable, but generally the whole hand is clumsy, stumpy; there is incurving of the fifth finger; relative shortness of thumb and fifth finger as compared with the index and fourth finger: the main lines on the palm are obliterated or broken up and replaced by many secondary ones, and there are horizontal lines running across the palms, close to the finger clefts, and the thumbs are slightly rotated inward; deformities, such as webbed fingers or double fingers. Their limbs quickly become cyanosed with dry skin. The whole foot is short and clumsy. There is a marked gap between the first and second toes, and a deep line running from this gap on the plantar surface. The big toe seems larger and out of proportion to the rest. Flatfoot is common. Chilblains are frequent.

All Mongols are dwarfs. The average age at death is six to seven years. Acute illnesses respond very slowly or not at all to therapy. A patent foramen ovale of the heart is very common. Various authors are agreed that a certain arrest of development takes place at the base of the skull.

Investigation of Fifty Cases of Mongolian Idiocy.—Dora M. Berry (*British Journal of Children's Diseases,* October-December, 1924) analyzed a series of fifty Mongolian idiots. Little evidence was obtained to support the prewar theory that Mongolianism was due to the mother reaching the end of the childbearing period. Much evidence was obtained that it was the father who was sexually defunct, as in two thirds of the cases he had served in the War, and in nearly half he had suffered from shell shock, while the mothers were young and healthy.

Gastroenteroptosis in Children; Its Relation to Recurrent Vomiting with Ketosis.—DeWitt H. Sherman and Edward C. Koenig (*Archives of Pediatrics,* September, 1924) conclude that recurring vomiting attacks in children are frequently due to gastroenteroptosis, either a simple mechanical abnormality or one markedly influenced by perverted nervous reactions. Recent rôntgenological studies have shown many new facts concerning the motility of the gastrointestinal tract. Where the condition is pronounced. posture, rest or support are essential for a cure. If gastroenteroptosis is the cause of the recurring attacks of vomiting the relief or prevention by means of a properly applied and fitting support is dramatic. The only time to cure gastroenteroptosis and its symptoms is in young children. It can merely be relieved but not cured in the adult.

In the authors' cases, the gastroenteroptosis was moderate, the enteroptosis and dilated tortuous sigmoid being more marked, especially the latter. In the older children, this tortuosity favors constipation and stagnation with fermentation and putrefaction.

An Epidemic of Diphtheria in an Immunized Group of Children.—R. P. Forbes and Berryman Green (*Archives of Pediatrics,* September, 1924), present the following observations based on a study of an epidemic of diphtheria in a childcaring institution.

The routine administration of toxin-antitoxin insures a low morbidity and mortality. There were only eleven cases of diphtheria among 135 children, of which two were extremely doubtful, and no deaths or complications.

It is not a safe or economical procedure to omit the Schick test after the administration of toxin-antitoxin. Fifteen cases or 16.8 per cent. of those immunized six months or more before the epidemic were Schick positive. The high percentage may have been due to faulty technic in performance or reading of the test or to poor toxin-antitoxin. The possibility of Schick negative persons developing diphtheria must always be kept in mind. Of the eleven cases recorded, six were Schick negative, but only three of these were typical of pharyngeal diphtheria and one received no antitoxin. A group of five children presented both positive Schick tests and positive throat cultures, but developed no diphtheria. All of the typical clinical cases had their tonsils and 43.67 per cent. of the contacts showing positive cultures had tonsils.

Medicolegal Notes.

HOSPITAL NOT LIABLE FOR NEGLIGENT WRAPPING OF HOT WATER BOTTLE BY PATIENT'S PHYSICIAN

The Wisconsin Supreme Court holds, Kuglich v. Fowle, 200 N. W., 648, in an action against a hospital and a physician to recover damages for a burn from a hot water bottle wrapped by the physician and placed in the plaintiff's bed to induce perspiration where the liability of the hospital was predicated upon the fact that it was the duty of the nurses to wrap the bottles, and that the hospital was responsible for the negligent wrapping, that the hospital could not be held liable, although the physician, who was the plaintiff's physician, was also an officer of the corporation owning the hospital and the real manager thereof.

POWERS OF DIRECTORS OF PRIVATE HOSPITALS UNDER NEW YORK MEMBERSHIP CORPORATION LAW

The New York Appellate Division holds, Van Campen v. Olean General Hospital, 210 App. Div., 204, 205 N. Y. Supp., 554, that hospitals established by certain municipalities under the New York statutes are public hospitals. Corporations organized by permission of the Legislature undertake to perform similar duties. They are supported mainly through voluntary gifts. These are private corporations. That they are engaged in charitable work for the benefit of the public, and thereby affected with a public interest, does not make them public corporations. The fact that they may receive a donation from the government to enable them to carry on their work, or funds from a city or county to care for sick, disabled indigent persons, does not affect their character as private institutions.

It is held that the Olean General Hospital, a nonstock corporation organized under the General Corporation Law and Membership Corporation Law, whose affairs are in many respects regulated by statute, whose directors and officers may receive no pay except under certain circumstances, and which is subject to visitation, inspection and supervision by the state board of charities, is a private corporation, although it is exempt from liability for negligence to patients and is exempt from taxation.

There being no provision in the corporation's by laws for a hearing prior to removal or suspension of one of the visiting staff, it is held that none is required. The selection and retention of physicians to treat patients admitted to the hospital are held to be matters of judgment and discipline. "The power to appoint," the court says, "usually implies the authority to remove. In common experience instances are not unusual where some physician disagrees with hospital management. When such disagreement becomes so pronounced as to interfere with orderly management and discipline, and when there is persistent violation and disobedience of necessary rules and regulations, we think the directors may bring the inharmonious conditions to an end by summary action. They are not required, in our judgment to give notice and conduct a trial in every such case."

EVIDENCE OF PHYSICIAN'S WEALTH INADMISSIBLE IN MAL- PRACTICE CASE—DEGREE OF SKILL AND CARE REQUIRED

The New Jersey Supreme Court holds, Smith v. Corrigan 126 Atl., 680, that in an action for damages against a physician for malpractice, evidence of the physician's wealth i inadmissible, even though punitive damages be demanded i the complaint, unless there is evidence of malice or wrongful motive toward the plaintiff on the part of the defendant The court in its syllabus also says that it was error to charg a jury that a physician responding to a call impliedly engage to employ the degree of skill and knowledge ordinarily exercised in his profession by physicians of good standin practicing in the locality and similar localities. The ski and care a physician is required to give a patient, the cou holds, is that ordinarily possessed and exercised by others i the profession.

RIGHT TO PERFORM OPERATIONS IN HOSPITAL

The Maryland Court of Appeals holds, Emergency Hosp tal of Easton v. Stevents, 126 Atl., 101, that a hospital whic has been enjoined from interfering with the performance o operations by a physician is guilty of contempt of court i refusing permission to perform such operations, althoug subsequent to the decree of injunction it had amended i constitution and by-laws in such a way that the physicia had no right thereunder to operate in the hospital without th approval and consent of the hospital staff, which he had n obtained.

RIGHT TO TAKE DEPOSITIONS IN MEDICAL BOARD'S INVESTIGA TIONS UNDER MISSOURI STATUTE

The Missouri Supreme Court holds, State v. Shot, 2 S. W., 804, that in the exercise of its police power th legislature has the right to vest in the state board of heal the power to investigate and license physicians, to investiga charges against a licensed physician, and in proper cases revoke such license. Missouri Rev. St. 1919, §7336, not on empowers the board to hear and determine the charges, b says that it may consider depositions in the course of su hearing, and, if an investigation is pending before the boar testimony for the purpose of the hearing "may be taken deposition to be used in evidence," in the same manner depositions are taken to be used in evidence in civil ca When, therefore, there are pending before the board charg against a physician, and said physician has been given noti thereof, it is held that the pendency of such charges autho izes a notary public to take testimony by depositions, just such notary public is authorized to take testimony in a ca pending in a court. The right to take the deposition und section 5440, K. S. 1919, is not dependent upon the sufficien of the petition in stating a cause of action, since, if t petition states no cause of action, it may be amended wh the investigation is yet pending.

UNDER MISSOURI STATUTE EVIDENCE BEFORE STATE BOARD HEALTH MAY BE BY DEPOSITION

The Missouri Supreme Court holds, State v. North, 2 S. W., 678, that Rev. St. 1919, §7336, relating to the revo tion of physicians' licenses, does not confer power, even implication, upon the state board of health, in a proceedi to revoke a license for unprofessional conduct, to issue su poenas for witnesses at the physician's request. While ph sicians cannot be deprived of their licenses without d process of law, and this requires a hearing after due not to the party, the Missouri court holds that §7336 does violate the due process clauses of the state or federal C stitutions because it provides for the evidence to be su mitted by deposition rather than by the personal attenda of the witnesses. It is held that the section, which provi for a hearing upon evidence after due notice, and for judgment after such hearing and a court review of whole proceeding, gives to physicians ample means of mak a full defense to charges filed against them before the st board.

Coughs and Colds

that tend to linger and fail to respond to remedies usually employed, almost always owe their persistence to inability of the body to restore a physiologic balance. Restorative and reconstructive treatment is essential and the ideal remedy is

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

A third of a century's successful use of this widely employed reconstructive has shown countless medical men that Winter coughs and colds will not linger, if they use Gray's Glycerine Tonic Comp. from the beginning.

Used in doses of two to four teaspoonfuls three or four times a day, this dependable tonic not only increases the vitality and resistive powers of the whole body, but through its pronounced influence on the pulmonary circulation promotes the physiologic activity of the local tissues and enables them to overcome congestion and inflammation.

The Purdue Frederick Co. **135 Christopher St., New York**

Valentine's Meat-Juice

Whenever the **Stomach** from any cause **Rejects Food** or **Medicine, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** to **Restore** and **Strengthen.** In the **Depressing Prostration** following **Influenza,** and in the **General Debility** of **Phthisis, Valentine's Meat-Juice** is recommended by many practitioners throughout the world as invaluable in their treatment.

Influenza *and* Phthisis.

Dr. Boulland, *Paris, France:* "In an attack of La Grippe accompanied by complete lassitude, I used VALENTINE'S MEAT-JUICE. With this preparation I established an excellent appetite and restored my strength very rapidly."

E. H. Walker, *Resident Medical Officer Boro Isolation Hospital and Boro Tuberculosis Sanatorium, Derby, England:* "I have pleasure in stating that I have found VALENTINE'S MEAT-JUICE valuable in the treatment of soldiers discharged from the Army suffering from Pulmonary Tuberculosis."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Richmond, Virginia, U. S. A.

VALENTINE'S
PREPARATION
NUTRIO PERFICIT
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

S 160

Miscellany.

Scholarships in Mental Hygiene.—The Rockefeller Foundation has appropriated to the National Committee for Mental Hygiene the sum of $40,000 for the establishment of a series of scholarships in extramural psychiatry and psychiatric social work. These scholarships are designed to provide special training for physicians who have had previous hospital training in psychiatry but who wish to prepare themselves for extramural work in child guidance, delinquency, education, dependency, and industry; and for the training of social workers in social psychiatry.

The scholarships are open to physicians under thirty-five years of age, who are graduates of Grade A medical schools and have had at least one year of training in a hospital for mental disease maintaining satisfactory standards of clinical work and instruction. A longer period of hospital training is desirable. Applicants for the scholarships in psychiatric social work must hold a collegiate degree, be under thirty years of age, and be free to devote themselves to a period of professional work upon the completion of their training.

The course of training in extramural psychiatry will be kept sufficiently flexible to complement as closely as possible the previous experience of the scholars in psychiatry. Assignments for various lengths of time, for work under supervision, will be made to well established clinics handling problems of childhood and adolescence, delinquency (juvenile and adult), dependency, and industrial problems. Opportunity will be given to each scholar to study under supervision as many types and manifestations of behavior disorder as are commensurate with adequacy of study.

Scholarships will be awarded by vote of the executive committee of the National Committee for Mental Hygiene on recommendation of the medical director. Application blanks may be obtained from Dr. Frankwood E. Williams, 370 Seventh Avenue, New York, N. Y.

Infectious Diseases Abroad.—The following general summary, compiled from the monthly Epidemiological Reports of the Health Section of the League of Nations, supplemented, when possible, by more recent information from other sources, appears in *The Lancet* (London), December 6, 1924.

Plague.—In India this year the curve of plague mortality dropped to its lowest point in the last week of July, which is a few weeks later than usual. The curve has since risen steadily to an average of about five hundred deaths a week for the country as a whole. In the week ending November 15 no death from the disease was notified in the ports of Bombay, Calcutta, Karachi, and Madras, but there were three in Rangoon. As regards other parts of the world, the following is a list of countries or localities in which the disease has recently occurred: Europe: Crete (August), Greece, Naples, Paris. Asia: Beyrout, Ceylon, Dutch East Indies, Baghdad, Jaffa, Bangkok, Singapore. Africa: Algeria (August), Canary Islands, Gold Coast, Madagascar, Mauritius, Nigeria (Lagos), Uganda, Union of South Africa. America: Ecuador and Los Angeles.

Cholera.—In India during August the reported cholera cases averaged about 8,050 a week and deaths 4,850. For the week ending September 27 the figures were 4,251 cases and 2,422 deaths. Very few cases have recently been reported from other parts of the world.

Yellow fever.—Sporadic cases continue to be notified from the Gold Coast and from ports of Mexico and other countries in Central America. It is estimated that at San Salvador there were sixty cases between June and September.

Typhus.—The typhus situation in Russia and Eastern Europe at present is believed to be more favorable than in any year since the war, but as regards most of the countries June is the last month for which full statistics are available. In Poland only 246 cases were notified during August: Esthonia, Latvia, Lithuania, Czecho-Slovakia, Jugo-Slavia, Roumania, and Bulgaria were almost or quite free from the disease. The most recent notifications from other countries are: Algeria, week ended October 31, four cases; Chile, wee kended October 13, twenty cases (at Talcahuano); Egypt, week ended November 11, fourteen cases, of which two were at Cairo; Italy, week ended September 28, one case at Sestoal Reghena; Malay States, week ended November 21, one case; Portugal, week ended October 18; one case at Oporto; Syria, week ended September 30, one case at Aleppo; Turkey, week ended November 8, one case at Constantinople.

Smallpox.—In general the smallpox situation abroad at present is decidedly favorable. Northern Europe (including Scotland and Ireland), the Baltic Republics, and Central Europe as far south as Roumania are almost or quite free from the disease, and it is declining in many other areas where it was prevalent.

Enteric fever.—In many countries enteric fever appears to have been more prevalent this summer than last. The increased summer incidence was particularly marked in the Baltic region (Sweden, Finland, Esthonia, and Latvia). In Denmark, however, only fifty-five cases were notified during August, as compared with 191 during the same month last year. In Germany, 1,967 cases were notified in the four weeks ending September 6, as compared with 1,680 during the preceding four weeks, and in Italy 1,159 cases during the week ending August 23, as compared with 373 cases during the previous week.

Scarlet fever and diphtheria.—In Germany and the Netherlands the incidence of these diseases during September was somewhat higher than last year. The following are a few recent statistics of deaths in certain cities: Paris, November 1 to 10, three deaths from diphtheria; Amsterdam, week ended October 11, one death from scarlet fever; Berlin, week ended September 27, two deaths from scarlet fever, three from diphtheria; Breslau, Cologne, and Frankfort-on-Main, week ended September 27, one death from scarlet fever in each; Leipzig, week ended October 25, three deaths from diphtheria; Munich, week ended September 27, two deaths from diphtheria; Budapest, week ended September 20, one death from scarlet fever, one from diphtheria; Warsaw, week ended November 8, ten deaths from scarlet fever, two from diphtheria.

For Accuracy in Diagnosis

use genuine "E. S. I. Co." Electrically Lighted Instruments

Special Outfit 60

Ophthalmoscope, Auriscope and Tongue Depressor, with Universal Battery Handle

To obtain proper service from our instruments, make certain you are using genuine "E. S. I. Co." lamps. For your convenience in ordering correct lamps, write for a copy of our Lamp Sheet.

Our twenty-five years of service to the Medical Profession and the fact that our instruments are made in accordance with the suggestions and with the co-operation of the eminent physicians and surgeons whose names they bear, is the best guarantee of their satisfactory character.

Nasopharyngoscopes—*Holmes.*
Transilluminators—*Sullivan.*
Bronchoscopic Instruments —*Jackson, Lynah.*
Cystoscopes—*Braasch, Young, Kelly. E. S. I. Co.*
Urethroscopes — *Swinburne, Young, Gordon, Koch, MacGowan, Ballenger.*
Rectal Instruments — *Tuttle, Lynch, Axtell, Bassler, Beach, Buie.*

Auriscopes, Nasal Specula, Tongue Depressors, Laryngoscopes.
Tungsten Batteries.
Socket Current Controllers.
Cautery Transformers.

These instruments are described and illustrated in the Ninth Edition of our Catalogue, mailed on request

ELECTRO SURGICAL INSTRUMENT CO.
ROCHESTER, N. Y.

Post-Operative Constipation

often causes extreme suffering and jeopardizes the efforts of the most skillful surgeon. The anesthetic, the shock of the operation, and in many instances the use of drastic cathartics before the operation, often produce almost complete paralysis of the bowel muscles. Peristalsis ceases and the fecal retention that follows, with the incidental formation of gas, invariably gives rise to severe pain and distress.

To avoid post-operative paresis and gas formation, AGAROL COMP. has been found invaluable. Given regularly a few days or a week previous to an operation, and its administration resumed as soon thereafter as circumstances permit, it may be confidently relied upon not only to produce evacuations without pain or distress, but to prevent the bowel sequelae and complications of surgical operations as no other remedy can.

REMEMBER—Agarol is the original Mineral Oil—Agar-Agar Emulsion, and is perfectly stable, odorless and palatable.

A liberal supply for testing AGAROL will be sent on request

Capital Punishment.—At a meeting of the Medico-Legal Society, it was proposed that the present method of execution should be exchanged for that of poisoning by coal gas, says an editorial writer in the *Medical Press and Circular,* October 29, 1924. And it was contended that its introduction into the condemned cell at night, while the convicted person was asleep, would lessen the anticipation of his doom and avoid the unpleasant spectacle of the scaffold. On the other hand it was objected that if he did not know the night on which he was to die, he would probably lie awake many nights in expectation, while if he were forewarned he would certainly not sleep, and would be slowly suffocated while conscious. There can be little doubt, that in experienced hands the present method of execution produces a quick, easy and painless death. The walk to the shed is but a few paces, and the whole is only a matter of seconds. If death is not actually instantaneous the victim immediately becomes unconscious. The very necessity of capital punishment requires that its infliction should act as a deterrent, and as a middle course between the publicity of the guillotine and the privacy of the Socratic method, there is probably none better than the present.

Tetraethyl Lead Poisoning.—Tetraethyl lead poisoning recently has attracted so much public attention that it is most important that this type of acute poisoning should be differentiated clearly by symptoms from ordinary chronic lead poisoning. The symptoms are absolutely different.

Tetraethyl lead poisoning recently has attracted an acute encephalopathy. Autopsies reveal an injection of the meninges of the brain, particularly at the base, with also some congestion of the cortex. The symptoms are both subjective and objective. The patient first complains of persistent insomnia, and usually of more or less nausea with vomiting. He feels restless and nervous and tired. He loses all appetite and begins to lose weight. Subjectively, one of the first symptoms noticed is a marked drop in systolic blood pressure, which frequently falls below 100 and sometimes below 90. There may be some diminution in the pulse rate, and in some cases a subnormal temperature. Lead is found in the stools, and some patients recently examined have shown stippling of the red blood corpuscles, although this is not invariably present. Considerable anemia develops, though no paralysis. In the extremely severe cases there is acute delirium of sudden onset, of the type familiar with delirium tremens. That is with violent jactitation, delusions of persecution, efforts to get up and run amuck, smashing through windows, and shouting with acute maniacal raving. Death ensues from exhaustion.

Tetraethyl lead is a remarkably active poison, taking first place among the metallic poisons. It was first made by chemists in 1854. Since that time there have been occasional instances of poisoning of greater or lesser severity among workers in chemical laboratories. Quite recently the possibility of using this substance in improving the efficiency of all gasoline motors, and thereby conserving the world supply of gasoline fuel by about one quarter has been discovered. Moreover, the addition of this substance to gasoline would make possible the use of high compression engines. Hence, the attempt to manufacture it on a commercial basis. It should be emphasized that it only can be used in gasoline motors in extremely diluted form, usually 1 to 1,000.

The possible dangers in the manufacture of tetraethyl lead, however, are three, namely: First, through direct absorption through the skin, which takes place with extraordinary rapidity; second, through inhalation of toxic fumes, and finally, through accumulation of ordinary lead dust, the latter being capable only of chronic lead poisoning.

The chemical substances used in the manufacture of tetraethyl lead are lead, ethyl chloride and metallic sodium.—(*Industrial Hygiene Bulletin,* December, 1924.)

Linacre, Harvey and Sydenham.—Exactly four hundred years have passed since the death of Thomas Linacre, at whose instigation the College of Physicians of London was founded by royal charter; two hundred and sixty-seven since that of William Harvey, the most illustrious of its fellows; and three hundred since the birth of Thomas Sydenham. They form a remarkable trio.

From first to last a scholar, and incidentally a physician, Linacre afterwards abandoned medicine for the Church. He will be remembered not as a physician, but for his success in procuring the charter which placed the medical profession upon a stable basis, and for his translations of the works of Galen from the unfamiliar Greek into the then language of science, by which means the knowledge of ancient medicine was first made available to criticism, and the spirit of doubt and inquiry was engendered. In the reign of Henry VIII there were no party politics. There was only one party—Henry himself: only one question—his supremacy. Had Linacre lived long enough to know the tyrant in his latter years, who can say but that he might have shared the fate of Fisher and More?

Harvey, on the other hand, earned a far greater fame—posthumous though it was by his discovery of the circulation. He, too, was physician to the reigning monarch, but Charles, much as he desired it, never attained the absolutism of Henry. At Edgehill and elsewhere Harvey was exposed to personal danger in his attendance upon his royal master, while the loss of his manuscript notes and observations when his London residence was plundered by the rabble, was no less than a national disaster. But before the struggle ended Harvey had withdrawn from practice and from participation in the royal cause, and his last years were spent in peaceful retirement. It is a remarkable coincidence that the two outstanding figures in the history of seventeenth century medicine should be found in opposite ranks. Whereas Harvey was an ardent cavalier, Sydenham was "a roundhead of a family of roundheads." After serving with the Parliamentary forces he returned to Oxford, and adopting medicine as a profession applied himself to the study and observation of disease. There is no doubt that he suffered in consequence of his political principles but, like Harvey, his last years were passed in retirement. Each lived long enough to witness the downfall of the party he had supported: but each died in his bed.—(*Medical Press and Circular,* October 29, 1924.)

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Rural Medical Service.—Since 1918 the New York State Department of Health has been more or less instrumental in securing physicians for seventy-two rural communities in which medical service has been either lacking or inadequate. When a request for assistance in securing a physician has been received, the District State Health Officer has been asked to investigate and report whether in his opinion the need was as stated and whether a physician could reasonably expect to make a living in the place. Upon receipt of an affirmative report, the name of the place has been included in a list which has been sent to physicians inquiring as to locations.

At present there are twenty-nine places listed as being in need of physicians. In several the prospect of the communities securing and retaining physicians is very poor unless some provision is made for subsidizing them. Reports of district state health officers indicate that one town in Essex County is paying a physician $2,200 annually; another in Essex County voted at town meeting to pay $1,500; one in Washington County expects to provide a bonus to a physician now located there, the amount not yet determined; in a Lewis County village a church contributed the use of its parsonage and in one town in Dutchess County the Supervisor has made an indefinite statement that the town would "do something" to secure a physician. Thus far in 1924, sixty-three physicians have asked for information and in seven communities physicians have been secured, in at least four instances apparently through the department's efforts.

This work has now been turned over to Dr. Joseph S. Lawrence, executive officer of the State Medical Society, 51 Chapel Street, Albany, N. Y.

Principal Causes of Death in 1923.—The Department of Commerce announces that 1,193,017 deaths occurred in 1923 within the death registration area of continental United States, representing a death rate of 12.3 in 1,000 population, compared with a rate of 11.8 in 1922. The death registration area (exclusive of the Territory of Hawaii) in 1923 comprised thirty-eight States, the District of Columbia, and fourteen cities in nonregistration States, with a total estimated population on July 1, 1923, of 96,986,371, or 87.6 per cent. of the estimated population of the United States.

The increase in the rates from influenza, from 31.4 in 100,000 population in 1922 to 44.7 in 1923, and from pneumonia (all forms) from 102.1 in 100,000 population in 1922 to 109 in 1923, accounts for nearly half the increase in the rate from all causes. Some of the other causes for which the rates increased are diseases of the heart, measles, cerebral hemorrhage, whooping cough, cancer, automobile accidents, nephritis, railroad accidents, and accidental falls. Decreases appear in the death rates from tuberculosis (all forms), diphtheria, malaria, and typhoid and paratyphoid fever.

Of the total number of deaths reported, were 170,033 from heart disease, 105,680 from all forms of pneumonia, 90,732 from all forms of tuberculosis, 87,707 from cerebral hemorrhage and softening, 87,378 from nephritis, 86,754 from cancer and other malignant tumors, 75,626 from congenital malformations and diseases of early infancy, and 74,131 from accidental and unspecified external causes.

Coughs and Colds

that tend to linger and fail to respond to remedies usually employed, almost always owe their persistence to inability of the body to restore a physiologic balance. Restorative and reconstructive treatment is essential and the ideal remedy is

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

A third of a century's successful use of this widely employed reconstructive has shown countless medical men that Winter coughs and colds will not linger, if they use Gray's Glycerine Tonic Comp. from the beginning.

Used in doses of two to four teaspoonfuls three or four times a day, this dependable tonic not only increases the vitality and resistive powers of the whole body, but through its pronounced influence on the pulmonary circulation promotes the physiologic activity of the local tissues and enables them to overcome congestion and inflammation.

DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

New Brain Disease Causes Japanese Epidemic.—A mysterious and unidentified disease has caused a severe epidemic in Japan which appeared first in provinces bordering the inland sea and then spread over the whole island empire. The first reliable reports of the outbreak have recently been received by the Health Section of the League of Nations at Geneva. The new disease was at first reported unofficially as cerebrospinal meningitis and then it was thought to be encephalitis lethargica, the socalled "sleepy sickness" which has been troublesome here and in Europe since the war. Finally it was found to be a hitherto unidentified epidemic disease involving the central nervous system, including the brain. The explosive character and the intensity of the new disease that appeared in July and continued in epidemic form at last reports surpass even the outbreaks of encephalitis and acute poliomyelitis, or infantile paralysis, which have been particularly acute in recent years. The incidence was nearly three per one thousand inhabitants in the most seriously affected province, Kagawa, and the mortality is reported as sixty per cent. This level of mortality is higher than that met in other serious disease such as encephalitis and poliomyelitis and approaches the fatality rate of deadly epidemic cerebrospinal meningitis.

The new disease is more likely to attack old people, particularly those over fifty years of age, than young, and more men than women are affected. Another remarkable feature is that more than one case per family or house occurs but rarely.

The central sanitary service of the Japanese Government and various medical colleges have investigated the new disease, but no causative microorganism has been found. No successful treatment has been evolved although the disease has been produced experimentally in rabbits.

The onset of the new disease is sudden and accompanied by a high temperature; after one or two days, loss of consciousness and a slightly maniac condition occurs. Either death comes in five to ten days or recovery is effected with a falling of temperature and regaining of consciousness.

Fatalities from Accidents During 1923.—The Department of Commerce announces that in 1923 practically one fifth of all fatalities from accidents were the result of automobile accidents. Approximately twice as many deaths from automobile accidents occurred in urban as in rural districts; a difference doubtless due, in part, to the greater number of hospitals in urban districts.

Of the thirty-eight states in the registration area, only three—Kentucky, Mississippi, and Wyoming—had higher mortality rates from railroad accidents than from automobile accidents. Wyoming had the highest mortality rate from railroad accidents, (34 in 100,000 population), and Massachusetts the lowest (3.5).

Wyoming also had the highest mortality rate from all kinds of accidents (195.4 in 100,000 population), and Mississippi the lowest (57).

California had the highest mortality rate from automobile accidents (32.6 in 100,000 population), and also from street car accidents (4.7), while Mississippi had the lowest rate from automobile accidents (4.4 in 100,000 population), and Wyoming had no deaths from street cars.

Of the sixty-six cities of 100,000 population and over, for which rates are shown, Camden had the highest mortality rate from automobile accidents (35.4), Buffalo the highest from street car accidents (8.9), and Scranton the highest from railroad accidents (16.4), and also from all accidents (144.5).

On the other hand, the lowest rate from automobile accidents (6.2) was for New Bedford, and the lowest rate from all accidents (47.3) was for Fort Worth, while Duluth, Jacksonville, San Antonio and Yonkers had no deaths from street car accidents, and New Bedford none from railroad accidents.

Of the 497 cities of 15,000 and over shown in the table attached, particular attention is called to the fact that no deaths from automobile accidents were charged against the following twenty-five cities, but here again the explanation of no fatalities in some cities may be the greater number of hospitals in larger cities nearby.

The Eyesight of School Children. — Only 4,227,702 of the 24,000,000 school children in the United States received eye tests in 1923, according to a preliminary report issued by the Eye Sight Conservation Council of America, embodying the initial findings of a nationwide survey of eye conservation in education and industry. The survey, which covers the results of testing the eyes of more than ten million students extending over a period of sixteen years, discloses, it is asserted, that the eyesight of children in the public schools throughout the nation is being neglected.

The data from which the Council's report was prepared were gathered from widely different sources, including reports of State Departments of Education and State Boards of Health since 1907, covering 6,600,000 eye examinations, and municipal reports since 1907 covering 3,500,000 examinations. The most recent statistics were obtained through data obtained from public schools of 247 cities, situated in the following eighteen states: California, Connecticut, Illinois, Iowa, Louisiana, Maine, Maryland, Massachusetts, Missouri, Nebraska, New Hampshire, New Jersey, New York, Ohio, Pennsylvania, Rhode Island, South Carolina and Texas. The other thirty states, it is said, conduct tests only in the schools of some of the large cities.

Simple visual acuity tests reveal that twenty-five per cent. of the school children in the United States have manifest defects of vision and symptoms of eyestrain. More thorough examination indicate that over fifty per cent. of school children have eye defect of sufficient degree to warrant correction. There is no uniform method for testing eyesight, says the report, which continues: "The reported percentages of total corrected and uncorrected eye defects vary all the way from 3.5 per cent. to 58 per cent. A city in New Jersey reported only 3.5 per cent. of 42,586 school children with corrected and uncorrected defective vision, a city in Missouri only 7 per cent. of 97,255, and a city in New Hampshire but 6.7 per cent. of 5,432. Such poorly conducted tests are of little value and the incorrect results are misleading.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. Its Bactericidal action is continuous, powerful

FORMAMINT stands apart from other bactericides designed for mouth and throat use because it exerts continuous action in the oral cavity.

Being in tablet form, Formamint as it dissolves liberates its main germicidal element — formaldehyde — which penetrates to the innermost recesses and folds of the mucous membrane. This germicidal action can be repeated at frequent enough intervals to make the treatment continuous.

Nontoxicity, freedom from irritating properties, and marked palatability are important features of Formamint. Their convenience of administration renders them a welcome and dependable agent for disinfecting the mouth and throat and maintaining oral prophylaxis.

We shall be pleased to place at the disposal of any member of the profession enough samples for a thorough test. Address The Bauer Chemical Company, Inc., 113 West 18th Street, New York City

GERM-KILLING THROAT TABLETS

Health Legislation, Sanitary Code Amendments, and Prosecutions During the Past Year.—A summary of the legislative activities of the Department of Health during the year 1923 appears in the August 30th issue of the *Bulletin* of the department. It should be remembered, in connection with all prosecutions undertaken by the Department of Health, that its main efforts are always directed to educational and preventive measures, and that the courts are only invoked as a last resource.

COURT ACTIONS

A comparison of court actions undertaken by the department during the year 1923 with those for the year 1922 shows an increase of 305 cases in the Court of Special Sessions, with a corresponding increase of $6,115 in fines, imposed for the year 1923. In the Municipal Term Court (Manhattan), during the same period, there was in increase of 556 cases disposed of, and an increase of $615 in fines. The Municipal Term, Borough of Brooklyn, 1923, shows 604 more cases than the previous year, with an increase of $6,302 in fines.

HEALTH LEGISLATION

A total of 3,862 bills introduced in both branches of the Legislature at Albany were examined for legislation affecting the interests of this department. It might be mentioned in connection with legislation that, at the request of this department, the Legislature, during the past year, amended the Labor Law so as to permit of the issuance of a sanitary certificate for bakeries which would remain in force until revoked by the Board of Health, in lieu of the provision which required the issuance of annual certificates.

SANITARY CODE AMENDMENTS

During the year 1923, seven amendments to the Sanitary Code were prepared and submitted to the Board for adoption. Such amendments related to the definition of x ray laboratories, the placing of dead horses on streets, the manufacture and preparation of sausages and of nonalcoholic drinks, the requirement that all persons handling food have medical certificates, the requirement for a permit to sell flavored water ices, and an amendment to the section standardizing ice cream to correspond with the State law on the same subject.

PROSECUTIONS

A number of very important convictions were obtained by the Department, including the conviction of a physician who was charged with having filed a false certificate of death in the Department. The physician in question stated in a certificate of death which he filed in this Department that the deceased, a woman of forty-four years of age, died of nephritis, edema of the lungs and endocarditis, when the deceased died of septicemia following abortion.

In several instances, appeals were made to the Supreme Court for orders directing the Board of Health to issue permits to various persons desiring to carry on business under permits from the Department and to whom permits had been refused by the Board. It is gratifying to state that, in every instance, the court sustained the contention of the Department in refusing the permits in question and throughout the past year the jurisdiction, power and authority of the Board of Health were completely sustained by the various courts.

Valentine's Meat-Juice

In **Hospital** and **Private Practice** and **in their own persons** when ill, **Physicians** have demonstrated the **Power** of **Valentine's Meat-Juice** to **Sustain** and **Strengthen** the **Weakened Vital Forces** when the **Digestive Organs** are **Impaired.**

Debility, Exhaustion *and* Anaemia.

Dr. Julian Calleja, *Pres. Royal Academy of Medicine of Madrid, Spain:* "It is with the greatest satisfaction I inform you that I consider VALENTINE'S PREPARATION OF MEAT-JUICE to be of a very superior order for invigorating the nervous system, for which I use it myself and prescribe it to my patients."

John Tanner, M. D., LL. D., *Senior Physician Farringdon General Dispensary for Diseases of Women and Children, London, England:* "In cases of Flooding or Hemorrhage of any kind, Fevers, low forms of Pneumonia, Extreme Exhaustion when the stomach is too irritable to retain any ordinary preparation, then VALENTINE'S MEAT-JUICE will be found to be a perfect God-send. I cannot speak too highly of it, as I have found it of such immense advantage to me in the treatment of the most anxious and serious cases under my care."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S
PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Deaths of Physicians in 1924.—During 1924, the deaths of 2,486 physicians in the United States were recorded in the *J. A. M. A.* Adding to that number two per cent. on account of delayed reports and possible omissions, we estimate the total number of deaths during the year at 2,536. On the estimate of 145,966 physicians in the United States, the number in the American Medical Directory, this is equivalent to an annual death rate of 17.37 per thousand. The death rate for 1923, according to *The Journal's* computation, was 17.95 per thousand, and the average for the last twenty-three years has been 16.94.

Ages.—The age at death of the 2,448 whose age was stated varied from twenty-two to ninety-nine years. Twenty-seven of the decedents were under thirty years of age; 113 were between thirty-one and forty; 331 between forty-one and fifty; 597 between fifty-one and sixty; 671 between sixty-one and seventy; 483 between seventy-one and eighty; 205 between eighty-one and ninety, and twenty-one between ninety-one and ninety-nine. The largest number of deaths at any given age occurred at sixty-five years.

Causes of Death.—Of the 2,433 deaths for which the causes were given, diseases of the circulatory system accounted for 893, the largest number. Some form of heart disease accounted for 518, and of these angina pectoris was specified in seventy; myocarditis in sixty-two; valvular disease in twenty-four; endocarditis in sixteen, and acute dilatation in fourteen. Cerebral hemorrhage accounted for 294 deaths, and was the second most frequent cause given. Diseases of the respiratory system caused 248 deaths, and of these 219 were due to pneumonia, six to influenza, and five to pulmonary edema. Diseases of the genitourinary system caused 165 deaths, of which number 117 were reported as due to nephritis and thirty-seven to uremia. Diseases of the digestive system caused 130 deaths, the largest number ascribed to one cause being thirty-two for appendicitis, then cirrhosis of the liver, twenty; peritonitis, seventeen; duodenal ulcer, thirteen, and gastric ulcer, ten. Of the 328 deaths due to so-called general disease, 138 were due to cancer, the organs most frequently affected being the stomach (twenty-one); intestine (sixteen); liver (ten); bladder (nine). Among the general diseases, tuberculosis was the second most frequent cause of death given with fifty-nine; then septicemia, thirty-nine; diabetes mellitus, thirty-five, and leucemia, ten. Diseases of the nervous system caused sixty-two deaths, twenty-eight of which were due to some form of paralysis; nine to meningitis; six to epidemic (lethargic) encephalitis; six to brain tumor, and four to some type of insanity. Seventy-nine deaths followed surgical operations. Five deaths were ascribed to fractures; four to carbuncles; six to aneurysm; ten each to thrombosis and embolism, and fifty-four to arteriosclerosis. For fifty-three deaths, no cause was reported.

Accidents and Homicides.—The causes and distribution of the 102 deaths due to accidents were: automobile, fifty-five; drowning, eight; falls, eight; firearms, five; grade crossings, four; poison, three; asphyxiation, three; street car, three; lightning, aeroplane, gas, phenol (carbolic acid), horse, and the roentgen ray accounted for the remainder. There were thirteen homicides, all due to firearms, and five of these physicians were killed by bandits.

Suicide.—Forty-five physicians ended their lives by suicide; twenty-eight, with firearms; five, poison; two jumping from high places; two, morphin; one, gas; one, hanging; one, chloroform, and in five instances the method was not reported.

Civil Positions.—Among the decedents, fifteen had been members of state legislatures; forty-six, members of boards of education; thirty-eight, members of boards of health; twenty-three, mayors of cities; twenty-one, coroners; fifteen, members of boards of medical examiners; thirteen, authors; four, lawyers; forty, druggists; 103, Civil War veterans; twenty-one, Spanish-American War veterans; 120, World War veterans; ten, bank presidents; two, judges, and one, a missionary.

Association Officers.—Two physicians who died in 1924 had been President of the American Medical Association; two, vice president; one, a member of the House of Delegates, and two, officers of sections. Eighteen had been president of state medical societies.—*J. A. M. A., January 10, 1925.*

To Promote Interchange of Health Authorities.—Interchange of the Public Health Officials of different nations is planned by the Health Committee of the League of Nations, according to a report to be filed with the Council of the League, a copy of which has just reached this country.

The first interchange this year will take place in March in Great Britain, where public health officials from several nations will spend seven weeks. The second interchange will take place in Belgium in May, and the third later in Yugoslavia. The Yugoslavian Government has offered to pay the traveling expenses of all who are the participants of this interchange.

The Japanese Government is making an arrangement for a similar interchange in Japan in the fall to coincide with the meeting of the Far Eastern Association of Tropical Medicine.

Other interchange plans are also under way; one for specialists and factory inspectors, and one for public health officers who have specialized in the protection of maternity and child welfare.

The value of this international cooperation in the improvement of public health has been so generally appreciated by the members of the League of Nations that the Assembly has tripled its appropriation for the work in the current year.

When the interchange conferences are held in highly developed countries like England or Belgium, it means that health officers from the more backward countries are given an opportunity to study the best practice of modern hygiene. When, on the other hand, the interchange is held in one of the old but less modern countries like Czechoslovakia, it means that the local health organization, which is just being organized, has the benefit of the advice and suggestion of the visiting health officers of the more highly developed countries.

NOVASUROL

Trademark Reg. U. S. Pat. Off.

Brand of **MERBAPHEN**

The Dependable Diuretic In Cardio-Renal Dropsies

When every other remedy fails in serious cardio-renal conditions a single injection of Novasurol often induces prompt and profuse diuresis with subsidence of edema.

The Improved Mercurial Injection for Syphilis

Novasurol is preferred by many syphilologists to other soluble mercurials, because of its high content of mercury but low toxicity, general painlessness of injections, prompt and prolonged action. It can be injected alone or mixed with arsphenamin.

HOW SUPPLIED: 1.2 c. c. ampules, in boxes of 5.

Pamphlet on Request

WINTHROP CHEMICAL COMPANY, Inc., 117 Hudson St., New York, N. Y.

Post-Operative Constipation

often causes extreme suffering and jeopardizes the efforts of the most skillful surgeon. The anesthetic, the shock of the operation, and in many instances the use of drastic cathartics before the operation, often produce almost complete paralysis of the bowel muscles. Peristalsis ceases and the fecal retention that follows, with the incidental formation of gas, invariably gives rise to severe pain and distress.

To avoid post-operative paresis and gas formation, AGAROL COMP. has been found invaluable. Given regularly a few days or a week previous to an operation, and its administration resumed as soon thereafter as circumstances permit, it may be confidently relied upon not only to produce evacuations without pain or distress, but to prevent the bowel sequelae and complications of surgical operations as no other remedy can.

REMEMBER—Agarol is the original Mineral Oil—Agar-Agar Emulsion, and is perfectly stable, odorless and palatable.

A liberal supply for testing AGAROL will be sent on request

Methods of Determining Extent of Thyroid Enlargement.—Dr. Robert Olesen, of the United States Public Health Service, conducted a thyroid survey of 47,493 elementary school children in Cincinnati last year. In presenting the results of this survey he says that the determination of the extent of thyroid enlargement is a matter requiring considerable practice as well as judgment. When the involvement is pronounced, there is little difficulty in classifying the relative degree of increase in accordance with prearranged arbitrary standards. When the degree of involvement is relatively slight, however, it is sometimes difficult to judge the matter accurately. Many methods of procedure have been advised by workers who are familiar with the subjects, and some of these are well worth recounting briefly.

Hertzler says that "ordinarily in average necks the normal thyroid gland is just palpable to experienced hands. If easily palpable, it is probably slightly enlarged. If palpable in a plump patient, it may be regarded as being enlarged. Often an increase in consistency is as valuable as evidence as increase in volume. Increase of sensitiveness, likewise, may be evidence of increased activity. During pregnancy these statements must be modified, for during this state not infrequently the thyroid gland is easily palpable in the normal state." Cabot maintains that the normal thyroid can rarely be felt.

The following procedure is recommended by Boothby: "To palpate the thyroid, grasp the right lobe with the left hand, thumb in front and fingers sinking in behind the posterior surface by approaching from behind the posterior border of the sternocleidomastoid muscle. By this method the anterior-posterior diameter can be quite accurately estimated and, by moving the hand up and down, the length of the gland can be determined. If an adenoma is present, it may frequently be sufficiently elevated out of the thoracic strait by instructing the patient to swallow so that the thumb and fingers can be slipped in beneath the tumor. The examination is facilitated by pressure of the other hand on the opposite side, pushing the gland and trachea towards the side being palpated."

When the presence of thyroid enlargement has been determined, it is necessary to use some means of comparative record. Mensuration is employed by many authorities, but is unsatisfactory because of the varying shapes of necks and the difficulty of placing the tape in the same position each time a measurement is taken. Hertzler believes that one does as well to employ more general terms, such as "palpable," to indicate the normal, "easily palpable," to indicate suspected enlargement, and "small," "medium," or "large" to indicate appreciable size.

Should mensuration be deemed desirable, the scheme devised by McCarrison offers a simple and efficient method. He advises that "in estimating the increase in size of the thyroid by measurement of the circumference of the neck, it is well to be aware of the fact that, in the absence of other factors, an increase of threefourths to one inch will represent a doubling of its volume, a further increase of threefourths to one inch a trebling, and a still further increase of onehalf to threefourths inch a quadrupling of the gland's volume. These figures are approximately correct for necks whose normal circumference is thirteen to sixteen inches."

In the Cincinnati survey it was the practice to view the side of the neck of each child in a good light. If the neck line was straight and the fullness peculiar to slight isthmial thickening was lacking, thyroid enlargement was presumably judged to be absent. However, before a final decision was made, the region of the usual isthmial location, namely, across the second and third, and, occasionally, the fourth ring of the trachea, was palpated by approximating the palmar surface of the middle finger. By a gentle up and down movement the isthmus can usually be felt and a decision made as to whether the thickening is sufficiently great to be recorded. With the finger still in position the child is asked to swallow, thereby causing the isthmus to be brought into bold relief beneath the finger. In very many instances the extent of isthmial enlargement may be determined by simple observation of the neck while the child swallows.

The Probability of Dying Eventually from Certain Diseases.—The right attitude toward the leading causes of death cannot be assumed from the published figures of crude deathrates. A better way of determining the emphasis upon research and upon organized effort for the control of the causes of human mortality is to find out how much the important diseases or conditions tend to curtail the life span of persons in the productive ages. This can be done only when adequate life table material is prepared from the crude published mortality data.

On this newer basis, heart disease leads the list of causes of death among males and females. The second disease, in point of its probability of terminating life, is chronic nephritis among males and cerebral hemorrhage among females. The disease next in order is cerebral hemorrhage for males and cancer for females. Cancer is in the fourth rank as a cause of death of males and chronic nephritis occupies this rank among females. Tuberculosis is fifth both among males and females. Lobar and bronchopneumonia are sixth and seventh in order, respectively, for both males and females.

The effort at present expended upon the study of heart, arterial, renal and malignant diseases, is insufficient compared with the amount of suffering, disability and death occasioned each year by these diseases. A program for the control of these conditions ought to be drawn on a scale commensurate with the nature and size of the task facing the newer public health movement. Further work is under way in this office with respect to the biological aspects of the chief causes of death, the distribution over the life span of the budget of deaths for given diseases and conditions in a life table generation, the concentration or dispersion of mortality over the ages of active, working life, the extent to which the burden of several causes of death at various age ranges has shifted, and the rise in importance of certain diseases or conditions, and the decline for others. The life table is a powerful tool of analysis of the chances of death, and such analysis leads to altered conceptions of the task facing the life conservation movement of the future. (*Statistical Bulletin,* Metropolitan Life Insurance Company, December, 1924.)

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Specialism.—Within the last few years the process of the division of labor has been proceeding apace in medicine and surgery, says the editor of the *Medical Press and Circular,* January 7, 1925. This is sufficiently attested by the fact that the Royal Society of Medicine already numbers twenty odd sections. No one can doubt that this differentiation is all for the good of medicine and surgery, for it is obvious that if a doctor devotes special attention to one branch of his profession, and is constantly observing and treating patients suffering from a special class of disease, he must be in a better position to acquire skill in their diagnosis and treatment than if he devotes himself to general medicine, general surgery, or general practice. In order to achieve a tithe of what is expected of him the general practitioner would need to be chosen from the very élite of the profession.

This process of differentiation is a natural and healthy one, and is indeed an essential feature of evolution. The danger the specialist has to guard against is a tendency to exaggerate the importance of his special branch, and to regard it as the most important of all branches of the healing art—that to which all others are subsidiary. This danger is well recognized, but for all that it is not always avoided.

The writer goes on to say that if he were asked to state the relative importance of the different forms of specialism in our profession, he would have no hesitation in placing preventive medicine—eugenics and hygienics—first. To two other branches would be given a foremost place, namely, disorders of the digestive system and gynecological disorders.

Four Decades of Progress in Diphtheria Control.—The deathrate from diphtheria has responded quickly to the medical discoveries which have been made during the past thirty years for the control of this disease. The first significant contribution of medical science to the control of this important menace to child life was Von Behring's discovery of antitoxin. In the period immediately following the general introduction of this adjunct in the treatment of diphtheria, 1894 to 1905, the deathrate in twenty-three American cities declined at a rate of 10.4 per cent. a year. Then there came a period of diminishing returns. Between 1905 and 1918, the rate declined only on the average of 2.8 per cent. a year. This was about the same rate of decline which prevailed during the decade immediately preceding the discovery of antitoxin.

In 1918, however, the new era of Schick testing and the administration of toxin antitoxin began, and with it there set in a further acceleration in the rate of fall of the diphtheria deathrate. During the period 1918 to 1923, the diphtheria rate fell on the average of 10.3 per cent. per year.

The diphtheria prevailing during the past six years in these twenty-three American cities exhibits also a new characteristic in the natural history of the disease. Under former conditions, the diphtheria deathrate tended to rise and fall in three or four year cycles. During the past six years, the deathrate has declined almost by uniform annual decrements. In fact, if the prevailing rate of fall continues in the immediate future, we may expect a negligible diphtheria deathrate in the year 1930. (*Statistical Bulletin,* Metropolitan Life, December, 1924.)

A New Scientific Journal.—Announcement is made by the National Research Council that the Rockefeller Foundation has appropriated $350,000 to finance a new scientific periodical to be known as *International Biological Abstracts.* The object of this periodical is to give in condensed form a monthly summary of all publications in the fields of botany, zolobacteriology and kindred subjects. There are at present two similar but smaller journals covering parts of the field, *Botanical Abstracts,* and *Bacteriological Abstracts.* The new periodical will absorb and replace these, and in addition cover scientific territory at present not taken care of. The expenditure of the $350,000 initial endowment will take care of editorial and office expenses for ten years, so that subscriptions will need to support only the actual costs of printing and distribution. Publication will begin in January, 1926.

Carrier of Plagues.—Spread of plagues into regions as yet free from them is a danger that threatens with the increased use of airplanes in long distance traffic, according to Air Commodore David Munro, of the British air service. In his presidential address to the Society of Medical Officers of Health, Commodore Munro pointed out that though there is at present no yellow fever in India, the species of mosquito instrumental in its spread is abundant, and that it would require only one fever patient to start an epidemic there. Similarly, an air borne victim of sleeping sickness from Africa might start the disease in some other tropical region at present unvisited with this scourge. At present, with the bulk of travel carried in steamers, quarantine rules are comparatively easy to enforce, but the development of air traffic wipes out sanitary frontiers as effectively as it does military ones.

Smallpox and Vaccination.—In the February 2nd issue of *Health News,* the New York State Department of Health publishes statistics, compiled by the Division of Communicable Diseases, which illustrate in a vivid manner the relation of vaccination to the prevention of smallpox.

The average morbidity rate for smallpox in the State, exclusive of New York City, in the years 1914-1924, inclusive, was 7.6 in 100,000 population. Under the existing law vaccination is a prerequisite to school attendance in first and second class cities only. A larger proportion of the populations of these cities has therefore been vaccinated than in the rest of the State. In first and second class cities, the average rate for smallpox was only 3.1 in 100,000 as compared with a rate of 9.6 in the rest of the State. It is quite certain that the difference would have been even more marked had there not been a laxity in past years in enforcing the vaccination law in private schools located in first and second class cities.

Other evidence of the efficacy of vaccination is furnished by the vaccination histories which were obtained in 487 out of the 488 cases reported in 1924. Of these, 451 had never been vaccinated, 33 were vaccinated more than seven years previously, two had been vaccinated six or seven years previously, and one was vaccinated in 1922. While it is not possible in the State as a whole to obtain figures showing the relative attack rate among unvaccinated persons as compared with those who have been vaccinated, general knowledge as to the large proportion of people who have at some time been vaccinated makes the above findings most significant, especially when the difference between the rates for first and second class cities and for other places is taken into consideration.

The fact that three individuals contracted the disease despite their having been vaccinated within seven years, again reminds us that there is nothing sacred about the number seven in connection with vaccination. As will be noted, one individual had been vaccinated two years before and yet contracted smallpox. The only safe way is to be revaccinated with potent virus until only an immune reaction results.

The Danish Gold Treatment of Tuberculosis.—Hardly a year passes but announcement is made of some new method of treating tuberculosis. The hope that springs eternal in the breast of the consumptive is stimulated again, only to end in the apparently inevitable disappointment that has ensued so frequently. The most recent method to receive the sensational publicity duly accorded any venture in the treatment of tuberculosis is a preparation of gold, advanced in Denmark under the name "sanocrysin." As reported in the *Ugeskrift for Læger,* meetings were held in Copenhagen, October 28th and 29th at which investigators of the new remedy gave their results to the Danish medical profession. Professor Moellgaard, the originator of the remedy, described its production, and stated that no reaction follows the introduction into the body of this remedy by the intravenous method, provided the tissues are healthy; but if they are tuberculous, a violent reaction ensues. It is assumed that the reaction is the result of the release of material from tubercle bacilli that are destroyed by the remedy. The reaction is opposed by the injection of a specially prepared horse serum which, Moellgaard believes, already has greatly reduced the severity of the phenomena of the reaction. At the conference in Copenhagen, Moellgaard described the complete clinical recovery of two monkeys with severe tuberculous infection, following the use of his method. Several well known Danish clinicians reported brilliant results in the cases of many patients. However, there were several instances in which death had followed the administration of the remedy, presumably on account of difficulty in determining accurately the proper dose. In discussing this work, the *British Medical Journal* points out that the most cautious of the speakers was Professor Moellgaard himself, and that he had been exceedingly reserved in his forecasts of the efficacy of "sanocrysin." In any event, it is also reported that Professor Moellgaard has asked the Medical Research Council of Great Britain to organize an investigation of the properties of the remedy. No doubt, information will become available in the near future which will indicate more adequately whether or not the drug has any real virtues in a condition in which heretofore all remedies heralded as specific have failed.—*J. A. M. A.,* December 13, 1924.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

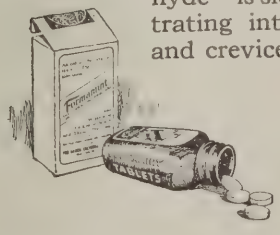
A germicide exerting *continuous action* in the oral cavity

MEMBERS of the profession appreciate the difficulties of successful treatment in tonsillitis or infection of the mouth or throat cavity, because of the usual lack of continuous action on the part of the therapeutic agent.

Formamint, being in tablet form, helps to overcome this difficulty. As the tablet dissolves and disintegrates its main germicidal element—formaldehyde—is slowly liberated, penetrating into the minute folds and crevices of the mouth and throat. This germicidal action can be renewed at frequent enough intervals to make the treatment continuous.

Formamint tablets are harmless and pleasant to the taste. Their convenience of administration renders them a welcome and dependable agent for disinfecting the mouth and throat and maintaining oral prophylaxis.

We shall be pleased to place at the disposal of any member of the profession enough samples for a thorough test. Address: The Bauer Chemical Co., 113 West 18th Street, New York City.



Formamint
GERM-KILLING THROAT TABLETS

Infantile Paralysis.—More than eight hundred cases of infantile paralysis, many of which occurred in adults, were reported to the State Department of Health last year according to Dr. LeRoy W. Hubbard, orthopedic surgeon of that department. He states further that altogether during the past four years over two thousand known cases of this disease have occurred and he estimates that there have been as many more so mild as not to have been recognized.

International Cancer Commission.—A commission to study cancer, composed of international medical authorities, has been appointed by the Health Committee of the League of Nations. The commission will consist of Sir George Buchanan as chairman, and Dr. Lutrarie, an Italian; Dr. Jitta of the Netherlands, Professor Leon Bernard and Dr. Carriere of France.

The first work of the commission will be a comparison of the statistics of Great Britain, Italy and the Netherlands relating to the cause of the difference shown to exist between the cancer mortality of these countries. The Cancer Commission was further empowered to extend its investigations into the epidemiology of cancer in general as far as possible.

So far European medical authorities have discovered that there is more cancer in England than in Italy and that there seems to be an inverse relation between cancer and birth rate. This hypothesis seems to be borne out by the fact that in the United States women of Italian birth, according to Dr. Eichel, have more children and less cancer than women from the British Isles.

Strong as a Horse.—This expression, spoken admiringly of a mighty athlete, is not so great an exaggeration as it sounds. Exact studies of the physical exertion put forth by the members of the famous Yale crew of 1924 by Dr. Yandell Henderson and Dr. Howard W. Haggard of the department of applied physiology at Yale, show that each man developed, during the period of a race, about one half horsepower.

Determinations of energy expended were obtained in various ways. The men were exercised individually on rowing machins with power meters attached; the ratio of oxygen taken in to carbon dioxide given off in breathing was determined; the racing shell they used was towed by a power boat with a spring balance set into the towline. "The data from these three methods were in general in fair agreement," says Dr. Hendrson. "They indicate that the maximal power exerted is from .45 to .55 horse power a man, or expressed in the heat equivalents, 4.8 to 5.9 calories a minute, with a total energy expenditure of 19 to 29 calories a minute, or thirteen to twenty times the basal rate."

It was noted that these athletes did not puff and blow noticeably, however great their exertion, which is in marked contrast with the distress of untrained or half trained men. The amount of oxygen they took in through their lungs reached about the limit of the carrying power of heart and blood; yet it was not sufficient to replace the amount burned up during the race. As Dr. Henderson expresses it, "He draws heavily on his credit and incurs oxygen deficits; these deficits are repaid by the high rate of oxygen absorption for a time after the work is ended."

New Publications Received.

(We shall publish in future full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we shall review those in which we think our readers are likely to be interested.)

Coughs and Colds

that tend to linger and fail to respond to remedies usually employed, almost always owe their persistence to inability of the body to restore a physiologic balance. Restorative and reconstructive treatment is essential and the ideal remedy is

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

A third of a century's successful use of this widely employed reconstructive has shown countless medical men that Winter coughs and colds will not linger, if they use Gray's Glycerine Tonic Comp. from the beginning.

Used in doses of two to four teaspoonfuls three or four times a day, this dependable tonic not only increases the vitality and resistive powers of the whole body, but through its pronounced influence on the pulmonary circulation promotes the physiologic activity of the local tissues and enables them to overcome congestion and inflammation.

Miscellany.

Periodicity, Affinity, and Antagonism.—The periodicity of disease is no new theory, and the remarkable cyclical character of influenza to which attention has recently been drawn, is but another exemplification of its reality. The present epidemic began during the first week in January—twice thirty-three weeks from the beginning of the epidemic of October, 1923; thrice thirty-three weeks from the beginning of the epidemic of February, 1923; and five times thirty-three weeks from the severe outbreak of the winter of 1921-2. The periodicity is exact, but incomplete. During the last few years, at least, this phenomenon has characterized influenza, but it is as yet unaccounted for.

The history of epidemics shows that they have a tendency to stamp their peculiar features upon other forms of contemporary disease. When diphtheria or scarlet fever is prevalent, nonspecific sore throats are common; when cholera or typhoid is epidemic, nonspecific enteritis increases. The toxicity of the bacillus appears to be diminished in some cases by an antitoxin, which prevents specific infection, but allows of irritation of those very tissues for which the bacillus shows its predilection. The eclectic habit of the bacillus is not understood. Why does diphtheria choose the tonsil? Why typhoid the intestine? The field of thought which is opened up by these questions is very wide; and there is another closely related problem which still more gravely concerns us.

The bacillus of influenza is suspected by many to be concerned in the production of the syndrome known as encephalitis lethargica; and its complicity in the recent outbreaks of pneumonic plague in China, Northern Africa, and California, is well nigh certain. The presence of influenza in each of these countries was already recognized, when suddenly cases occurred in which, instead of pursuing the ordinary course, septic pneumonia rapidly produced a fatal issue. It was pneumonic plague. The mortality was almost cent. per cent., and the infection, spread probably by droplets of expired air, was of extreme virulence. The bacillus of influenza appears to have been powerful enough to induce its comrade of plague to concentrate upon the lung, with results so speedily fatal that bubonic infiltration had not sufficient time to develop. The natural resistance of the individual infected would have been sufficient, in at least some cases, to overcome the onslaught of either influenza, or plague, singly; but in combination the attack upon the lung was irresistible.

To us sleeping sickness is a new disease; probably it is due to some change in the elective affinity of the bacillus; but the causative factor, like that of most new diseases other than those of occupation, is undiscovered.

The historian of medicine, puzzled to account for the absence of traces of syphilis from the disinterred bodies of the ancient Egyptians, and indeed from the whole of the Old World previous to the very end of the fifteenth century, seeks from the study of the evolution of disease and the changes which it undoubtedly undergoes in consequence of external social conditions, an explanation of the disappearance of leprosy and the contemporaneous rise of syphilis. If the recent outbreaks of pneumonic plague were due to the alliance of the bacilli of influenza and plague, is it not permissible to assume the occasional antagonism of other forms, and the consequent defeat and disappearance of one of the contestants? Were they to meet in the ring today, what would be the result of the struggle between the bacillus of leprosy and the spirochæte?—(*Medical Press and Circular,* February 24, 1925.)

Type Specimens of All Bacteria to Be Preserved at McCormick Institute.—A museum containing a complete collection of living disease germs, as well as useful bacteria, is to be established at Chicago. Such a comprehensive collection of type cultures will be to the bacteriologist what the herbarium is to the botanist. The herbarium enables the botanist to identify his plants by comparing them with the dried specimens. The type collection serves not only to identify new cultures by comparison with authentic ones, but since they are living cultures they can be used by investigators, manufacturers of biological products, clinicians, and others who want a particular organism for a special purpose.

For many years what was known as the Kral collection was maintained in Germany by private enterprise, but this has not been available since the beginning of the war. More recently the British Medical Research Council has established a type collection at the Lister Institute and in Holland there is a collection of fungi. The American Museum of Natural History established a collection of bacterial type cultures under the direction of Dr. C. E. A. Winslow, curator of public health. This was maintained for some time after Dr. Winslow severed his connection with the museum, but the necessity for curtailing expenses finally obliged them to abandon this activity. The collection was taken over by the Society of American Bacteriologists which maintained it at the Army Medical Museum in Washington. Owing to the limited funds available it was only possible to carry a limited number of bacteria and no attempt was made to include molds, fungi, or other microorganisms. In the meantime, the National Research Council was endeavoring to find some permanent source of support for the collection and finally the General Education Board recognizing the value of a collection of this kind to medical schools and other institutions teaching bacteriology, made a grant of $24,000 to support the collection for five years.

Under this arrangement the collection will be maintained at the McCormick Institute at Chicago, of which Dr. L. Hektoen is director. The general management of the collection will be vested in a committee representing the Society of American Bacteriologists, the Society of Bacteriologists and Pathologists, the American Phytopathological Society, the American Society of Zoologists, and the McCormick Institute. The chairman of the committee is Dr. L. A. Rogers of the United States Department of Agriculture.

It is proposed to enlarge the scope of the collection as much as the funds available will permit. It will include not only the pathogenic bacteria, but also bacteria causing plant diseases, those used in dairying and the fermentation industries, soil and nitrogen fixing bacteria. A limited number of molds and fungi may be added and eventually the collection may include some of the protozoa or animal forms.

THE AMERICAN NAUHEIM

OPEN THE YEAR ROUND

The GLEN SPRINGS

WATKINS GLEN, N. Y.

THE attention of the medical profession is invited to the superior facilities offered by The Glen Springs for the reception of guests requiring rest, dietary and hygienic regulation under experienced medical supervision.

ESPECIALLY suitable for reference by physicians are the following conditions:—

CONVALESCENCE FROM RECENT ILLNESS
CARDIO-VASCULAR DISTURBANCES
RHEUMATIC CONDITIONS
CHRONIC FATIGUE STATES

THERE is no hospital or institutional atmosphere about The Glen Springs—a feature appreciated by physicians when recommending appropriate guests. Members of family or friends who might accompany referred guests will also find restful enjoyment during their stay.

A splendid golf course, delightful walks and other outdoor amusements are available under proper conditions.

THE facilities include Nauheim Baths, given with natural calcium chloride brine; equipment for hydrotherapy, electrotherapy and mechanotherapy—under specialized professional direction; clinical and X-Ray laboratories and electrocardiograph.

DURING PREGNANCY

an increase in the development of poisons within the expectant mother's body is inevitable. Therefore, interference with free elimination from the bowels always presents a special menace from the essential increase in the retention of toxins with all their possibilities for harm to both mother and offspring.

Fortunately, *in AGAROL COMP.* the practitioner has an ideal remedy, that not alone will afford prompt intestinal elimination, but used for a reasonable period, will soon restore the physiologic activity of the bowels, thus assuring normal evacuations that will follow regularly and thoroughly without the aid of further medication.

Entirely free from griping or pain, or any other objectionable effect, AGAROL can be used at any stage of pregnancy with every confidence in its safety and efficiency.

REMEMBER—Agarol is the original Mineral Oil—Agar-Agar Emulsion, and is perfectly stable, odorless and palatable.

A liberal supply for testing will be sent to physicians on request

The Stigma of Neurosis.—The evolution of official terminology from "madhouse" through "'lunatic asylum" to "mental hospital" shows that there is a great deal in names when they involve prejudice, and any change in nomenclature is justified that helps to remove the notion that the mental sufferer is a guilty encumbrance to be hidden away so that he cannot offend. But the expression of prejudice in names is still current in the sphere of those minor psychoses that rarely involve certification, says *The Lancet,* January 3, 1925. "Shell shock" was a respectable disability, whilst the alternative and correct diagnosis of hysteria was, and often still is, suppressed on account of the attached opprobrium. A patient may have a gastric or vasomotor "neurosis," but he must not be "neurotic" on pain of social or family ostracism and, we fear, some degree of professional neglect. There is, indeed, a distinction between neurotic and neurasthenic which involves a subtle moral judgment. If we accept inquest reports as a basis of observation we find that the sufferer from neurasthenia often commits suicide while the neurotic never does; thus the latter may demonstrate, by suicide, his right to the more respectable diagnosis. The phrase "nervous breakdown," however, involves nothing blameworthy, and a recent lay writer describes under that title the mental trouble from which the elder Pitt suffered, though the description makes clear that the condition was one of anxiety hysteria.

This medley of prejudice and pseudodiagnosis is partly responsible for that astonishing amount of suffering and disability in the domain of the psychoneuroses to which Dr. Edwin Goodall referred in a recent issue of *The Lance*. The obloquy carried by such words as "hysterical" or "neurotic" is accompanied by a belief that the patient is to blame, that he need only use common sense and will power to rid himself of his difficulties, and that neurotic suffering is best treated by "wise neglect." This belief will often be supported by the practitioner who has not followed the progress of psychopathology. It is regarded as a sad injustice when a patient with an organic disability is wrongly thought to be hysterical or neurotic, but, though an error in diagnosis is always regrettable, it is our peculiar attitude towards the neurotic that makes this particular mistake so distressing. Yet the denial of help to the mental sufferer is a greater injustice, and the patient who needs treatment for his mental state is often not even given the opportunity to describe the symptoms for which he would welcome relief.

This same medley is allowed to form the equipment with which many a practitioner, even after holding hospital appointments, sets out to handle the problem of the psychoneuroses in general practice. Systematic instruction in psychopathology hardly exists, though its foundations are now well established, and that it receives little attention in the general curriculum is suggested by the fact that the candidate for a qualifying examination would never expect to be questioned, say, upon that common clinical phenomenon connoted by the phrase "a nervous breakdown." In fact, his hospital training teaches him that all clinical interest ceases when once a diagnosis of neurosis is established. Certainly the neurotic patient seems to have a legitimate grievance, but it is one that bids fair to be removed or alleviated. More instruction is being given today in our medical schools along the indicated lines, as the teachers themselves are becoming more impressed with its necessity. And here we have a direction in which medical training can be improved practically without additions to a crowded curriculum.

School Inspection Started in Panama Canal Zone.—Beginning October 1, 1924, the annual examination of the school children of the Panama Canal was inaugurated. This is the first year that the public schools have had the services of a full time school nurse.

The examination of the school children in the Zone is perhaps done more thoroughly and scientificially than in any city in the United States. After the preliminary weighing and measuring of the child, he is then seen by specialists for the examination of the eyes, ears, nose and throat. The examination is thoroughly done with the use of the ophthalmoscope and other instruments. Next, the child is referred to a physician for the lungs and heart. The examination is made with the child stripped to the waist. In boys, examination is also made for adherent prepuce. A notice is then sent to all parents as to the defects discovered and they are advised to have corrections made at the Ancon Hospital where experts are on duty. During the summer 635 had corrections made, including vision, enlarged tonsils, adenoids and orthopedic defects.

Health centres are in operation where parents can come for further advice relative to their defective children.

Low Mortality Rate in the United States During 1924.—The year 1924 has won the honor of having had the lowest mortality rate ever recorded among the wage earning populations of the United States and Canada. Statisticians of the Metropolitan Life Insurance Company have announced that based upon returns from fifteen million records a substantial decline in death rate as compared with 1923 is assured, although all reports are not yet in.

Heart disease, as in 1923 and 1922, will be the leading cause of death but the mortality, nevertheless, will be much lower than in 1923. Since 1911 there has been a decline of twenty points in 100,000 in the heart disease death rate.

The great health achievement of the year has been the marvelous reduction in the death rate from pulmonary tuberculosis. The rate this year will be slightly over ninety in 100,000 persons exposed. This marks a decline of ten per cent. in one year. In 1911 the rate from this cause was more than twice the 1924 figure.

Pneumonia will be the third cause numerically. For the few diseases that show higher rates of mortality in 1924, either the increase has been small or the diseases themselves are of relatively minor importance numerically.

Present indications are that 1924 will be the first year since the automobile has become a means of transportation that the death rate from its casualties will not increase. Up to December 13th the 1924 rate was identical with that for the same time last year.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Death Rate from Cancer Increasing in England and Wales.—Statistics indicate that in these two countries out of each one hundred thousand persons 121 die of cancer. The rate gradually increased, from 0.32 in a thousand in 1851-60 to 1.21 in 1921. To some extent, this fourfold increase is due to the fact that a larger proportion of the population now lives to those ages at which death from cancer most commonly occurs. When allowance is made for this ageing, it appears that the increase recorded has actually trebled.

To what extent the increase is due to improved diagnosis and more accurate reporting has long been a matter of discussion. These factors have been contributory, but they do not account for the whole increase. Superficial cancers, such as those of the tongue and female breast, were readily recognizable even sixty years ago, by the time death occurred. Yet there have been increases of thirty-nine and twenty-eight per cent., respectively, in deaths from cancer in these locations in twenty years. During the same period, deaths from cancer of all forms, collectively, increased by twenty per cent. Only in cancer of the uterus has there been no significant increase.

During the twenty years from 1901 to 1921, in which cancer increased by twenty per cent., the general death rate fell back thirty-two per cent., that of infants by forty-five per cent., and that of tuberculosis by thirty-eight per cent. An increase of mortality attributed to cancer is the common experience of modern civilization. The frequency with which different parts of the body are attacked by fatal cancer differs greatly in different countries. It may differ over a period of years even in the same country. Changes are occurring in the ages at which most of the deaths occur.

In England and Wales the tendency is for the deaths to occur later in life than formerly, and this change has been going on, at least among females, for many years. The latest returns show that the death rate from cancer is not increasing from males up to forty-five years of age, or for females up to sixty. The most rapid increases are in extreme old age. As might be expected, differences in regard to the parts of the body attacked exist between the sexes.

Acute Poisoning Due to Eating the Seeds of the Jimson Weed (Datura Stramonium).—J. A. Garvin (*Archives of Pediatrics*, December, 1923) states that the diagnosis of poisoning due to eating the seeds of the Jimson weed is simple and is made from the widely dilated pupils, high fever, flushed body and wild delirium of sudden onset. The finding of the specific seeds in the vomitus or stools, or the history of having eaten seeds from a pod, confirms the diagnosis. The treatment consists in the prompt removal of the seeds by gastric lavage or emetics, and cathartics. The delirium is best controlled by restraint and an ice cap to the head; the fever by hydrotherapy and the physiological effects of the alkaloid by the hypodermic administration of pilocarpin or physostigmin in the appropriate dose for the age of the patient. Opium or one of its derivatives may be used in the early stages of poisoning, but it is contraindicated if depression occurs.

Coughs and Colds

that tend to linger and fail to respond to remedies usually employed, almost always owe their persistence to inability of the body to restore a physiologic balance. Restorative and reconstructive treatment is essential and the ideal remedy is

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

A third of a century's successful use of this widely employed reconstructive has shown countless medical men that Winter coughs and colds will not linger, if they use Gray's Glycerine Tonic Comp. from the beginning.

Used in doses of two to four teaspoonfuls three or four times a day, this dependable tonic not only increases the vitality and resistive powers of the whole body, but through its pronounced influence on the pulmonary circulation promotes the physiologic activity of the local tissues and enables them to overcome congestion and inflammation.

Miscellany.

The Rivers Memorial Medal.—The council of the Royal Anthropological Institute recently determined to commemorate W. H. R. Rivers, M.D., F.R.S., who was its president at the time of his death, by founding a Rivers Medal, to be given annually for meritorious anthropological work done in the field. The first presentation of the medal took place at a meeting of the institute on January 27th, when the award was made to Dr. Alfred C. Haddon, F.R.S., reader in ethnology in the University of Cambridge, in recognition of his work in New Guinea, Torres Strait, and Borneo. The president of the institute, Professor C. G. Seligman, in presenting the medal (which has been struck by the Royal Mint and bears a bust of Dr. Rivers on the obverse), said that the names of W. H. R. Rivers and Alfred Cort Haddon were closely united in many ways. In honoring both on this occasion anthropologists were praising famous men and—for he might well carry the quotation further—"our fathers that begat us." There was no one who had added anything to the science of anthropology during the last fifteen years who was not indebted to a greater or less extent to one or other or both of these men. They worked together, and personally he had no doubt that neither of them would have achieved what he did had he worked alone. The medallist of that evening, upon whom this honor was most naturally and fittingly bestowed, was the first man to organize a really important anthropological expedition in the field. Every working anthropologist, directly or indirectly, was under obligation to the initiative behind that expedition to the Torres Strait a quarter of a century ago. The expedition proved to be the most important that had ever been organized, and it was a striking proof of Haddon's foresight that he determined that it should be not only an anthropological but a psychological expedition also, and that half of its members should be trained psychologists. The opportunity of that expedition sent the subtle spirit of Rivers roving over that fascinating "no man's land" in which ethnology, psychology, genetics, sociology, and even medicine all interpenetrated. There he experimented to some extent, but more than anything else he speculated, and speculated brilliantly. Professor Seligman added that he had had the privilege of working with Rivers in the field, and he was able to see the very distinct connection between the genealogical method which he hammered out in Torres Strait and the work he did for shell shocked soldiers in the war. After speaking of the work of Dr. Haddon as author and teacher, he said it was with mingled respect and affection and sorrow and pride that he presented the Rivers medal for the first time. Dr. Haddon, in acknowledgment, said that he was very happy to have his name associated with that of his old friend and colleague. After his own first expedition of 1889 he gained an appreciation of the fact that psychology was an integral part of anthropology, and he determined that if he had opportunity in this direction he would not neglect it. When he was preparing for the Torres Strait expedition in 1898 he asked Rivers to join him, and Rivers refused, but later, finding that C. S. Myers and another of his best students were going, he changed his mind and asked to be allowed to join the party. The consequence was that for the first time natives were studied psychologically in their own country by trained psychologists with adequate apparatus.—(*British Medical Journal,* January 31, 1925.)

New Dietary Factor in Pellagra Prevention.—Pellagra, a disease of serious importance in the South, may be prevented by the newly discovered "dietary factor P-P," present in brewers' yeast, fresh milk, and fresh beef. While it may be a vitamine, it is not identical with any of the vitamines hitherto discovered and described. Dr. Joseph Goldberger and Dr. W. F. Tanner, of the United States Public Health Service, discovered this new disease preventing factor while they were at work at the Georgia State Sanatorium for colored women, where many of the inmates were sufferers from pellagra.

Earlier investigators had made frequent statements that peas and beans were pellagra preventives, but Goldberger and Tanner found that even when the patients were given these foods daily in considerable amounts, pellagra still developed. Then they tried fresh milk casein in the form of cottage cheese, and got good results. Dried milk powder, however, failed to have the same preventive power. The best results were obtained with brewers' yeast. Patients receiving daily doses improved more rapidly than those on any other treatment tried. By a comparison of the diets of their patients with those used in treatments and experiments on other deficiency diseases, Goldberger and Tanner were led to the conclusion that none of the known vitamines or dietary factors could account in every case for their results, and that therefore there must be a hitherto unsuspected preventive factor at work.

The Cost of Disease.—It has long been a truism that diseases like tuberculosis and typhoid fever, which kill in young adult life, impose a heavier economic burden than those which affect infants or old people. During the first two decades the family and the community make their investment; during the following forty years they reap the profit.

Freudenberg (*Zeitschrift für Hygiene,* xciii) has recently made an interesting attempt to work this problem out on a more definitely quantitative basis, by computing for Germany the mortality at each age period from each principal cause, and then applying assumed figures for the value of a human life at each age period. The six chief causes of death ranked in actual numerical importance as follows, expressed in percentages of deaths from all causes: diseases of the heart and arteries, 20.9; developmental diseases and malnutrition, 12.8; tuberculosis, 10.5; diseases of the digestive organs, 10.5; tumors, 10.0; pneumonia, 7.7. On the basis of economic cost the indicated relation is very different. Tuberculosis now leads accounting for 22.0 per cent. of the total economic burden of disease; diseases of the heart and bloodvessels come next with 19.3 per cent.; tumors account for 12.6 per cent.; and diseases of the digestive system for 7.0 per cent. Pneumonia falls to 5.3 per cent. and developmental diseases and malnutrition to 3.3 per cent. There is a viewpoint here which may well be taken into consideration in planning the strategy of the public health campaign.—(*The Nation's Health,* February, 1925.)

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

An invaluable aid for strict oral disinfection

THE oral cavity, being an ideal habitat for pathogenic micro-organisms, naturally forms an avenue of invasion for infection.

As a remarkably effective means of combating these micro-organisms, Formamint fulfills a definite and much needed function.

Being in tablet form, Formamint can be held in the mouth where it will dissolve slowly in the saliva, and give off nascent Formaldehyde which penetrates to the innermost recesses and folds of the mucous membrane. This germicidal action can be repeated at frequent enough intervals to make the treatment continuous.

Formamint tablets are harmless and pleasant to the taste. Their convenience of administration renders them a welcome and dependable agent for mouth and throat disinfection and prophylaxis.

We shall be pleased to place at the disposal of any member of the profession enough samples for a thorough test. Address The Bauer Chemical Company, 113 West 18th Street, New York City.

Formamint
GERM-KILLING THROAT TABLETS

Venereal Disease in the United States.—An increase in the number of cases of venereal disease reported in the United States in the year which ended June 30, 1924, over the number reported in the previous corresponding year is disclosed by the figures recently made public in the annual report of the Division of Venereal Diseases of the United States Public Health Service. The report indicates that the increase in the fiscal year 1924 amounts to 27,382 cases, or 7.2 per cent. A total of 363,063 cases of venereal disease were reported to the various state boards of health from all sources. This total was composed of 193,844 cases of syphilis, 160,790 cases of gonorrhea, and 8,429 cases of chancroid.

"The fact that the 1924 statistics show an increase over those for 1923 does not necessarily mean that venereal disease was any more prevalent in the United States last year than in the year before," explains the chief of the Division of Venereal Diseases.

"The greater number of cases now on record at the State boards of health," he continues, "may well be accounted for by the increased efficiency in detecting these maladies and by more conscientious reporting of cases on the part of private physicians. For a long time the danger from syphilis and gonorrhea was greatly enhanced by the fact that these diseases were carefully covered and concealed and were often kept secret even from physicians who might have brought about a cure. Fortunately people are now learning that they must go to a reputable physician or clinic if they wish to be cured, and laws requiring that these cases be reported to the State boards of health are making it possible to obtain some idea as to the prevalence of syphilis and gonorrhea in the country, although there are many cases that still escape discovery.

During the fiscal year just passed, 504 public clinics reported to the State boards. These clinics treated 118,023 new cases of venereal disease made up of 65,046 cases of syphilis, 49,029 cases of gonorrhea, and 3,949 cases of chancroid. A total of 2,147,087 treatments were given. The fact that these clinics made 302,152 Wassermann tests for detecting syphilis and 203,008 examinations to discover gonorrhea would seem to indicate that people are beginning to realize the terrible consequences that follow in the wake of these diseases and are willing to take advantage of reputable opportunities for cure.

Reports from thirty-seven correctional and penal institutions were received by the division. The efforts of those in charge of these institutions have resulted in a large increase in the number of venereally diseased persons discovered and treated. New patients to the number of 7,045 were admitted to treatment in 1924, an increase of forty-four per cent. over the year 1923.

The menace of venereal disease is one that is being fought by the United States Public Health Service and the various State boards of health acting in cooperation with municipal health officers. These governmental agencies are trying to impress upon parents, teachers, young people and others the need of wholesome sex education, of prompt medical attention and the necessity for the passage of modern health ordinances and legislation. Among the social institutions which can aid in this work are the home, the school, the church and the press.

Miscellany.

The Mystery of Death.—In an address on Folk Medicine, delivered before the Leeds University Medical Society and published in the *Lancet*, February 7, 1925, William Murphy, M.B., Ch.B., of Leeds, says:

"To primitive man we may well believe that death was an insoluble mystery. Intellectual man has not yet discovered a wholly satisfactory explanation of death—or of life, although science has formulated and discarded many theories on the subject. The great French philosopher, Descartes (seventeenth century), actually believed that the pituitary gland was the bond between body and soul. One step forward, however, we have made. We have learned to regard death as a natural event. Primitive man—if we may draw conclusions from the beliefs of savage tribes still in existence—was quite unable to visualize it as a natural occurrence at all, possibly because in his experience it was so frequently associated with violence. He connected death with wild beasts, drowning, lightning, or—and this much more rarely—with mysterious affections of his body which he could not understand or account for. So he came to attribute death and all physical suffering to supernatural causes, of which there would seem to have been three of paramount importance: 1, The anger of offended spirits; 2, the supernatural power of an enemy; 3, the displeasure of the dead.

"Spirits to our unsophisticated forefathers were an everpresent source of trouble, and disease was long regarded as a mark of the wrath of those powerful beings. Among certain Asiatic tribes a favorite treatment for disease of any kind was for the village sorcerer to thrash the patient until the demon was driven out of him. In Burmah, if thrashing proved ineffectual, the doctor was wont to trample on his patient's abdomen until he killed the demon.

"In England the Devil was long credited with the power of inflicting disease and also, if he felt so inclined, of curing it. He seems indeed to have been held in some respect as the head of the medical profession—a view which doubtless still claims some adherents! Sir George Mackenzie, writing in the seventeenth century, states that 'the Devil can cure disease because he knows its natural causes better than the physicians can, who are not present when diseases are contracted and who, being younger than he, must have less experience.'

"The power of enemies was scarcely less dreaded than the wrath of spirits. A curse was a potent cause of death or misfortune, though most commonly the desired effect was only obtained by the mediation of some person skilled in the practice of magic. The witch—or wizard as it sometimes was, though more rarely in England—might compass the evil by means of incantations or prayers—usually addressed to the Devil—but sometimes she required for the success of her spells something intimately associated with her destined victim, like a lock of his hair or a piece of his clothing. It seems probable that the oldfashioned nurse's eagerness to commit at once to the fire such things as pieces of nails or hair arose out of nothing more hygienic than this old superstition. A method still more favored by the witches was the burning of a waxen or wooden image of the person upon whom the spell was to work, in the belief that as the wax melted or the wood charred so the body of the victim wasted or was tormented. The 'evil eye' was for centuries, and, indeed, in some places still is, an object of superstitious dread. One writer even tells us that the reason why surgeons do not show wounds to every man is that they have observed that the influence of some eyes hinders the process of healing.

"The belief that the dead could cause suffering to the living probably belongs to a much later stage in the history of culture than either the fear of spirits or of witchcraft, and it has survived both of them. It is still commonly thought that if a corpse be allowed to remain in the house over a Sunday there will be two more deaths in the family. As late as 1887 the body of a woman who had died of phthisis was exhumed and her lungs burned because she was believed to be drawing the remaining members of her family into the grave after her. This story, I perhaps ought to add, comes from America, where perhaps even popular medicine may transcend common experience, as does the length of the American appendix! The belief in vampires is probably akin to this fear of the dead, a belief not yet extinct even in the civilized world. So recently as a couple of years ago a case was reported from Central Europe in which the body of a dead woman was taken from the grave and a stake driven through her heart—that having been for centuries the recognized means of dislodging the evil creature which was using the dead body to pursue its hideous work.

"To say that all misfortune was attributed to one of these three great causes would, of course, be inaccurate, but they were the most potent influences for evil and the most dreaded."

Recovered Lepers Discharged from Leprosarium.—Four lepers who went to U. S. Marine Hospital No. 66, Carville, Louisiana, the National Home for Lepers, a few years ago, have been discharged, according to a statement made by Surgeon General Hugh S. Cumming of the United States Public Health Service. They are no longer a menace to the public health, the disease having been cured, or, according to official parlance, "arrested." The conditions under which lepers are released from this institution are exceedingly rigid. They require special observation for a period of one year, including monthly bacteriological examinations to show that the leprosy bacillus is absent from the tissues. Certification of cure is also required from a board of three medical officers stationed at the hospital and experienced in leprosy.

The treatment at Carville includes the use of chaulmoogra oil, special preparations of mercury used intravenously, x ray therapy, surgery of superficial areas of involvement, hydrotherapy, and the violet ray. The results of treatment have been sufficiently encouraging at this institution to induce numerous other patients, of whom there are believed to be several hundred in the United States, to agree to their transfer. A special car fitted up for the purpose, and carrying a doctor and a nurse was used in the transfer last week of eleven patients from Florida, and seven were brought from California. There are at present 236 leper patients at Carville.

THE AMERICAN NAUHEIM

OPEN ALL YEAR

The GLEN SPRINGS

WATKINS GLEN, N. Y.

WM. E. LEFFINGWELL, President

THE attention of the medical profession is invited to the superior facilities offered by The Glen Springs for the reception of guests requiring rest, dietary and hygienic regulation under experienced medical supervision.

ESPECIALLY suitable for reference by physicians are the following conditions:—

CONVALESCENCE FROM RECENT ILLNESS
CARDIO-VASCULAR DISTURBANCES
RHEUMATIC CONDITIONS
CHRONIC FATIGUE STATES

THERE is no hospital or institutional atmosphere about The Glen Springs—a feature appreciated by physicians when recommending appropriate guests. Members of family or friends who might accompany referred guests will also find restful enjoyment during their stay.

A splendid golf course, delightful walks and other outdoor amusements are available under proper conditions.

THE facilities include Nauheim Baths, given with natural calcium chloride brine; equipment for hydrotherapy, electrotherapy and mechanotherapy—under specialized professional direction; clinical and X-Ray laboratories and electrocardiograph.

RAILWAY communications:

On the Pennsylvania, Lehigh Valley and New York Central railroads. Connection at Elmira with the Lackawanna and Erie.

Bowel Atonicity

is a common affliction of faulty diet, advancing years, or the "cathartic habit." The intestinal muscles become sluggish and lose their power, as a consequence of which, the bowel contents are delayed in their passage, over-absorption takes place, and the feces become hardened and reduced in bulk.

In AGAROL COMP.—a palatable, carefully balanced combination of pure mineral oil, agar-agar, and phenolphthalein—the practitioner has a remarkably efficient remedy for correcting the foregoing conditions and permanently restoring the functional actvity of the bowel.

As a result of its use, not only, therefore, does Agarol Comp. give remarkable satisfaction as an evacuant, but regularly employed, it soon restores conditions within the intestinal canal essential to its muscular tone and natural activity, and thus enables the bowels, after a reasonable period, to act normally and regularly without further aid or assistance.

AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbance; not habit forming.

The Shape of the Skull.—A Lecture on "The Cause of Skull Shapes" was delivered by Dr. Arthur Robinson, professor of anatomy in the University of Edinburgh, under the auspices of the Royal Anthropological Institute, in the rooms of the Geological Society, Edinburgh, on January 19th. He drew attention to the fact that the cranial and facial parts of the skull varied in shape and size at different periods of life, and that it was now generally admitted that the size of the cranial part depended on the amount of its contents. Since in normal circumstances these contents were mainly brain, it followed that the size of the cranium depended on the size of the brain. On the other hand, the cause of the shape of the cranium was still a matter of dispute, and a satisfactory explanation had to account, not only for differences in proportion, but also for the formation of localized expansions which were numerous and varied.

The two principal factors which might be assumed to have effect on cranial shape were environment and heredity. Environment might be considered to include the associated effects of climate and altitude and the immediate environment of the muscles attached to the skull bones. With regard to general environment, there was a fairly common idea that a special type of head was being evolved in America, but there was no definite proof that such was the case. It seemed impossible to avoid the conclusion that the shape of the skull depended mainly upon hereditary tendencies which worked under the law of genetic control. If that was the case, then the shape of the cranium depended upon the growth of the brain, and the growth of the brain was undoubtedly governed by the laws of heredity.—*British Medical Journal,* February 7, 1925.

Progress Made in Control of Cancer.—Dr. Howard Canning Taylor, of New York, professor of clinical gynecology at the College of Physicians and Surgeons, and president of the American Gynecological Society, was elected president of the American Society for the Control of Cancer at the annual meeting of the society held on March 7, 1925. Dr. Taylor, who has been the Society's vice-president and chairman of its executive committee, succeeds Dr. Charles A. Powers, deceased. Thomas M. Debevoise was reelected secretary and Calvert Brewer was again elected treasurer. Dr. Francis Carter Wood was elected vice-president.

In the annual report of Dr. George A. Soper, managing director, evidence was presented to show that the efforts of the society to acquaint the public with the early symptoms of cancer had borne fruit throughout the country. The latest report of the Pennsylvania Cancer Commission showed that in Pennsylvania from 1910 to 1923, the average time between the first symptoms and operation in superficial cancer cases had dropped from eighteen months to fourteen and six tenths months, and that the average time between which a patient consulted a physician and was operated on dropped from thirteen months to four and five tenths months. Where deep cancers were concerned, the results were even more striking. Twelve years of educational work had cut down the average time between the discovery of the first symptoms of superficial cancer and the first call on the doctor twenty per cent., and reduced the interval between the patients' first appearance at the doctor's and the beginning of medical treatment sixty-five per cent. in superficial cancer and seventy per cent. in deepseated cancer.

Reports from the fifty-three State chairmen of the society had shown that in each State patients were coming earlier to physicians and consequently with a better prospect of cure. Specific instances could be quoted of lives saved through the society's work. The society's efforts for the year had included systematic work among the public, members of the medical profession, nurses, dentists and students at medical colleges. The society's publications had all been revised to contain the latest information. Exhibits had been made at many notable meetings of professional men and women.

With reference to clinics, the cornerstone of a permanent institution had been laid in connection with the Medical School of the University of Minnesota, the funds having been provided by Mrs. George Chase Christian, a member of one of the society's committees. A temporary clinic had been successfully operated at Fall River, Massachusetts, under the direction of Dr. E. P. Truesdale of that city, aided by Dr. Francis Carter Wood.

In coöperation with the Connecticut Medical Society, the Connecticut Public Health Association and the Connecticut State Department of Health, the society had begun a three years' campaign in Connecticut during which it will turn to account the experience it has gained elsewhere in the matter of cancer control.

The director's report showed that inquiries for information have greatly increased during the twelve months. They included letters from physicians of England, Spain, Cuba and Italy who wished information to guide them in the conduct of campaigns for the control of cancer in their countries.

Dr. Soper recommended that during the coming year work be continued along present lines and broadened in some directions; that "cancer weeks" be generally held; that further efforts be made to enlist the coöperation of dentists, nurses and social workers; that the work undertaken in Connecticut be extended to other States, and that the survey conducted by the Philadelphia Cancer Commission be duplicated elsewhere in the country.

China Needs More Doctors.—The *World's Health,* January, 1925, calls attention to the urgent need for more Chinese doctors in China. Existing hospitals are seriously understaffed; private practitioners are relatively few; the number of doctors engaged in public health work is neglible; research work is in its infancy, and the death rate is very high. Under these circumstances the China Medical Board of the Rockefeller Foundation has requested the Council on Health Education to undertake a campaign for more doctors through the schools and universities, and has offered a total sum of $22,500 for a five year period to cover expenses. The council has agreed to undertake the campaign and a committee has already been appointed. Its plans include a survey of possible sources of medical students, a campaign to interest schools and scholars in a medical career, competitive prizes for essays on medicine, and scholarships to first class medical schools in China.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Leprosy.—Sir Leonard Rogers has recently pointed out that the prevalence of leprosy is connected with damp heat, and that consequently tropical countries are most seriously affected, says the *Medical Press and Circular,* December 10, 1924. Of the estimated world statistics of leprosy, a number placed at three millions, one tenth are within the British Empire, and, of this tenth, two thirds are inhabitants of India. The tragic figure of the leper is there to be found in all grades of society from the rajah to the ryot. Of these only about four per cent. are in institutions, large numbers living in the rural districts where little medical aid is available and many cases of women and children are hidden away in zenanas. The need is emphasized of an increase in the number and size of existing institutions, the compulsory segregation of its victims, and the provision of facilities for treatment by the latest methods. The disease is said to be spreading in Africa, where the Mission for Lepers has established homes from which many patients have already been discharged free from active symptoms. A considerable number of such cases has been recorded in India, Korea, the Philippines and Brazil, where, in the single State of Para, it is estimated that there are 3,000 cases. Belem, the largest focus of leprosy in South America, has 1,700 lepers in a population of 120,000.

Health Hazards in the Manufacture and Use of Chlorine and Chlorine Products.—Thousands of tons each month of chlorine and bleaching powder are manufactured and used in the factories of New York State. There is more bleaching powder made in New York State than in all the rest of the United States put together, says the *Industrial Hygiene Bulletin* of the New York State Department of Labor. A survey of all New York State bleaching powder factories revealed the fact that this industry has gone back to the old process which was introduced into this country in 1879 and which has called forth legislation in England. During the past three years many paper factories and textile mills have given up the use of bleaching powder and are buying liquid chlorine in tank cars. The liquid chlorine is absorbed in milk of lime or a soda solution to make the bleaching liquid. The hazard of corrosive dust is thereby completely eliminated and the quantity of poisonous gas discharged into the air is comparatively nil. Although liquid chlorine is a highly poisonous chemical, it has been handled with remarkably few accidents. Efficient and well safeguarded apparatus has in general been provided. Large quantities of this poison gas are used in the metropolitan area of New York City.

Average Criminal Mentally Diseased.—More than half of ten thousand criminal delinquents examined by the National Committee for Mental Hygiene have been found to be mentally diseased, feebleminded, or otherwise mentally abnormal. This number includes inmates of prisons, reform schools, and those on probation to the courts. As a result of this examination Sing Sing will establish a psychiatric clinic to study each prisoner upon entering. The subnormal will be segregated from the normal and kept under state control. Massachusetts has passed a bill requiring the psychiatric examination of all prisoners sentenced for more than thirty days and those arrested more than once.

Valentine's Meat-Juice

Whenever the **Stomach** from any cause **Rejects Food** or **Medicine, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** to **Restore** and **Strengthen.** In low forms of **Pneumonia** and **Exhaustion,** in the **General Debility** and **Depressing Prostration** following **Influenza** it is recommended by many practitioners throughout the world as invaluable in their treatment.

VALENTINE'S PREPARATION
NUTRIO PERFECTA
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Pneumonia *and* Influenza.

William H. Peters, M. D., *Admitting Physician, Camp for Consumptives, State of Rhode Island, Providence, R. I.;* "VALENTINE'S MEAT-JUICE was the only nourishment retained by my five-year old daughter during an attack of Pneumonia. I consider that it saved her life and believe it to be the best product of its kind."

Cavalier Dr. Enrico Ballerini, *Late Surgeon to the Hospital of Rome, Italy:* "I have used VALENTINE'S MEAT-JUICE in the treatment of patients, and also personally, after having been very ill with Influenza, and I must say it is an excellent tonic in conditions of great organic weakness. It is also very agreeable. I have prescribed it with the greatest satisfaction for convalescents and invalids restricted to a liquid diet."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

Miscellany.

Germicidal Rays.—A study of the germicidal action of ultraviolet rays, covering the range of wave lengths from just beyond the limit of the visible spectrum down to the shortest wave lengths emitted by a mercury vapor arc in a quartz lamp, shows that the shortest waves have the most pronounced and vigorous action, being capable, when sufficiently intense, of producing death with an exposure of only one second, says the *Medical Press and Circular,* March 4, 1925. Longer wave lengths required a greater intensity and acted much more slowly, but a fatal result ensued from waves as long as 365 millionths of a millimetre, which is the approximate length of the shortest waves visible to the human eye. Rays of sufficient intensity can kill bacteria (Bacillus coli communis) with an exposure of less than one second in duration, the requisite minimum intensity being obtained at a distance of six inches from the lamp. When the intensity is very low the effect is greatly retarded, and in some experiments an exposure of from seventy-five to eighty seconds was required. With still lower intensities there was some indication that the bacteria were stimulated instead of being killed. It was also found that the germicidal effect was proportionate to the total exposure, whether given all at once or divided into several short exposures with intervening periods of rest.

Tobacco and Efficiency.—By far the most important contribution yet made to our knowledge of the physiological and psychological effects of smoking, says the *Nation's Health,* March 15, 1925, is the recent monograph by C. L. Hull [*The Influence of Tobacco Smoking on Mental and Motor Efficiency.* Psychological Review Co., Princeton, N. J.] reporting the results of an exhaustive investigation carried out in the psychological laboratories of the University of Wisconsin.

Previous work, admirably summarized by Professor Hull, has clearly indicated that smoking causes an increase in heart rate (Payne) and interferes with the precision of neuromuscular reactions (Blickley, Lang, Johnson, Froeberg). Studies in regard to the effect of tobacco upon muscular fatigue and upon mental efficiency have, on the other hand, been more or less unsatisfactory, either as a result of paucity of data or of lack of adequate control.

In Hull's work eighteen subjects were used, half of them habitual smokers and the other half nonsmokers. The problem of control was admirably taken care of by an ingenious procedure which apparently eliminated any possible effect of suggestion. The fundamental test dose was the smoking of a large pipe of mild tobacco for a period of twenty-five minutes. During this period the subject was blindfolded and on the nontobacco days there was placed in his mouth an empty pipe equipped with a heating coil and containing a little moist asbestos plaster. The subject, placidly drawing in warm moist air through this apparatus, and smelling the pipes of other subjects in the room was quite unable to tell whether he was smoking tobacco or not. Indeed these innocent victims of diabolical psychological ingenuity had no idea that they were not smoking every day.

The outstanding results from this investigation were to show that, so far as physiological processes are concerned, smoking, under the conditions used, markedly increases the pulse rate and markedly increases tremor of the hand, confirming and extending the results of earlier observers. In the psychological field, the result which emerges with most complete statistical force is an influence upon speed in addition, unfavorable in the nonsmokers, favorable in the habitual smokers. The results of other tests, though statistically less convincing, lead the author to suggest that ordinary routine thinking is favored by tobacco while the formation of new associative bonds is hindered.

Dr. Hull has made it clear that an habitual smoker's pipe stimulates his heart but interferes with the steadiness of his hand.

Mortality of Physicians.—Casper, in 1835, found from statistics that physicians were the shortest lived of all the professions and occupations he had investigated, and ascribed the fact to the great demands on physical and mental strength that were associated with the habit of life, says the *Medical Press and Circular,* March 4, 1925. His conclusions, however, have not been generally accepted since the basis upon which his method was founded was unscientific. Later researches by German physicians and statisticians proved that during the second half of the nineteenth century, the mortality of medical men was somewhat lower than that of the male population as a whole, but considerably higher than that of the other academic professions. More recently, Freudenberg has published an article on the subject based upon statistics from 1920 to 1923. He first compared the medical mortality with that of German males during that period, secondly with the medical mortality of fifty years ago, and thirdly, with that of English physicians during the same period. Thence it appears that the mortality from infectious diseases, especially typhoid, typhus, and tuberculosis, is much less than formerly, and very noticeable is the decline in affections of the nervous system.

In members of the academic professions, venereal diseases are frequent, this being attributed to comparatively late marriage. The central nervous system in brain workers seems particularly nonresistant to syphilis; and, in addition, there is the well known predisposition to general paralysis and tabes among Jews, who are well represented among German physicians. The great progress in the prophylaxis and treatment of syphilis has greatly diminished the medical mortality from that disease and its sequelæ.

The number of deaths from pneumonia and pleurisy has decreased, and those from tumors remain stationary in number. From fifty-five to sixty-five years of age, affections of the circulatory organs are more common among physicians than the general population.

The effects of the war have been manifested in a higher mortality among the older age groups, and an increase in suicide is probably due to the same cause. Of 217 physicians, sixteen committed suicide, owing for the most part to financial difficulties. In his comparison with English medical men, the latter showed a lesser mortality from tuberculosis, but a much greater from arteriosclerosis; and the incidence of suicide is much lower in England than in Germany.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

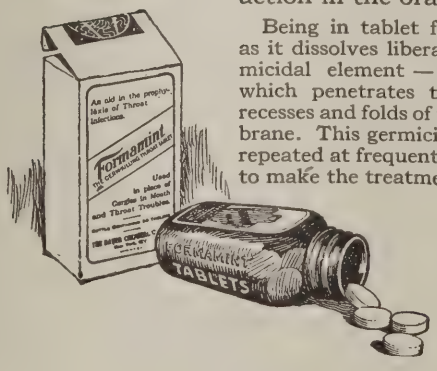
Its Bactericidal action is continuous, powerful

FORMAMINT stands apart from other bactericides designed for mouth and throat use because it exerts continuous action in the oral cavity.

Being in tablet form, Formamint as it dissolves liberates its main germicidal element — formaldehyde — which penetrates to the innermost recesses and folds of the mucous membrane. This germicidal action can be repeated at frequent enough intervals to make the treatment continuous.

Nontoxicity, freedom from irritating properties, and marked palatability are important features of Formamint. Their convenience of administration renders them a welcome and dependable agent for disinfecting the mouth and throat and maintaining oral prophylaxis.

We shall be pleased to place at the disposal of any member of the profession enough samples for a thorough test. Address The Bauer Chemical Company, Inc., 113 West 18th Street, New York City



Formamint
GERM-KILLING THROAT TABLETS

South American Doctors Study Health Conditions in the United States.—Nine medical officials from Central and South America are in the United States in response to the invitation issued by Dr. H. S. Cumming, surgeon general, United States Public Health Service, to begin a two months' study of health conditions in the United States. Several weeks will first be spent in the Southern states looking into conditions there. This is part of the interchange of health officials provided for by the League of Nations. Last year Switzerland acted as host; the next country visited will be Jugoslavia. The work of the United States Public Health Service in guarding against epidemics, the work of state medical boards, and public hygiene questions will be given most of the visitors' attention.

Racial Mortality Statistics.—The remarkable differences in mortality exhibited by different race stocks in the United States offer some of the most puzzling and the most fascinating problems which confront the American sanitarian—problems with which no other country has to deal on quite so large a scale. The admirable volume recently issued by the census bureau, *Mortality Statistics, 1910-1920,* contains some of the most suggestive data along this line which have ever been made public, says the *Nation's Health,* March 15, 1925.

The figures cited below for New York State in 1920 are entirely typical of those presented for other states, Pennsylvania for example checking almost perfectly. They indicate that the adjusted death rate at all ages is low among persons of native birth and German birth, high among persons of Italian birth and highest among persons of Irish birth. The fairly low German rate is however due to a very low mortality in infancy (much lower than among the native born), balanced by a high mortality in old age. The Italians show an exactly reverse condition, a high infant mortality, overbalancing a low mortality in old age. The Irish, on the other hand, suffer from an excessive mortality all along the line and therefore show an enormously high adjusted rate.

DEATHS IN 100,000 IN NEW YORK STATE

Mother nativity	*Adjusted*	*Under one year*	*65-74 years*
United States	1,214	10,870	4,582
Germany	1,258	7,010	6,184
Italy	1,386	11,399	4,778
Ireland	1,751	11,184	8,116

Among the most interesting of these racial idiosyncrasies is that which manifests itself in relation to tuberculosis and pneumonia. Thus in New York State the adjusted death rates among persons of native birth were seventy-seven for pulmonary tuberculosis and 130 for all forms of pneumonia; among persons of Italian birth the tuberculosis rate rose to ninety-six and that for pneumonia to 242; while among persons of Irish birth the tuberculosis rate was 184 and the pneumonia rate 188. These figures are no accident. In state after state we find the same thing, pulmonary tuberculosis twice as high among the Irish as among the Italians but acute respiratory disease higher among the Italians than among the Irish. It seems very difficult to explain this phenomenon on the ground of any social or environmental differences. It would seem rather to be related to inherited constitutional susceptibilities.

Valentine's Meat-Juice

In **Typhoid, Gastric** and **Other Fevers,** where it is **Essential** to **Sustain** the **Patient** without **Irritating** the **Weakened Digestive Organs, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** of **Restoring** and **Strengthening** when **Other Food Fails.**

J. R. Wood, M. D., *Physician Sheltering Arms Hospital, Paint Creek, W. Va., U. S. A.:* "I have been using VALENTINE'S MEAT-JUICE in the treatment of Typhoid Fever cases in the Sheltering Arms Hospital, for the last two or three weeks, with the most gratifying results both to the patient and physician. I consider it the best preparation of animal food I have ever seen, in fact, the only one I have ever had any success with."

Dr. Genevaix, *Assistant Surgeon-Major, First Class, Hotel Dieu, Creusot, France:* "The patients to whom I have given the excellent preparation, VALENTINE'S MEAT-JUICE, have found their general condition rapidly improved by it, and in the convalescence from continued Fever (Typhoid and Para-Typhoid) it gives the best results."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

VALENTINE'S
PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

The Eyes in Hot Climates.—In a paper on Ophthalmology in Egypt, read at a recent meeting of the Section of Tropical Medicine of the Royal Society of Medicine, Mr. A. F. MacCallan, at one time director of the Egyptian Government Ophthalmic Hospitals, gave some valuable instruction on the care of the eyes in hot climates. While fatigue, ill health, and worry bring out latent defects in the eyes in any country, a hot climate causes greater fatigue than a temperate one, and this fatigue, he pointed out, may lead to fatigue indigestion with resulting physical depression. Worry, whether of official or of private origin, similarly may cause ill health. Under these conditions he found that trifling errors of refraction, or slight degrees of heterophoria, exerted effects quite out of proportion to their actual severity, and he emphasized the importance of careful correction of these errors, generally under a cycloplegic such as homatropine. In a highly sensitive patient, whose nerves were constantly being jarred by physical or mental discomforts, the correction of a very small degree of astigmatism might make all the difference between happiness and misery. In a country such as Egypt, the healthy emmetropic eye of the European becomes painfully affected by the sun's glare in the summer when motoring or riding along dusty roads or over the desert. It is the heat rays from the red end of the spectrum which cause this. To prevent the effects of glare, Mr. MacCallan advises the wearing of protective goggles of Crookes B or B2 material; but if discomfort is complained of the refraction of the patient should be verified under a cycloplegic. There are, he states, other varieties of protective glasses, which theoretically are more absorbent of the heat rays than Crookes glasses, such as peacock blue, Fieuzal, and amber, but in his own experience of a large number of cases he found that ordinary glass in which was included, if necessary, a very small ametropic correction, was all that was required. Sun, dust, and wind might also cause pinguecula and pterygium. In dusty seasons it is most advisable to wash from the eyelids the dust which collects there and which may contain septic material. This should be done three times a day. In many cases he found this simple precaution sufficient to prevent constantly recurring attacks of conjunctivitis.—(*Lancet,* March 14, 1925.)

Importance of Physique and Correct Posture in Relation to the Art of Medicine.—W. A. Cochrane (*British Medical Journal,* February 23, 1924). maintains that according to his findings the teaching of anatomy should be put on a basis to include all the types of anatomical structure. This is evidenced by the patients who have not the normal structure. A study of physiology with reference to special structure should also be made. In the make-up of creatures so markedly different as the slender and heavy, there is sufficient of interest to note that the types apparently carry their own potential of disease. In the study of a large group of chronic patients it was noticed that tuberculosis and mental disorders of the acute type, the hyperglandular disturbances, chronic arthritis of the atrophic type, sympathetic hypertonus and neurasthenia, were commonly associated with the slender type. Arteriosclerosis, hypertrophic arthritis, chronic diseases of the kidney, gallstones, degenerative mental disorders and vagus hypertonus were with the heavy type of structure.

Problems relating to man's posture have a direct bearing on medical and surgical practice. Many of the chronic conditions requiring treatment represent a derangement of the mechanism which regulates and maintains the proper and correct posture of the body. The physical conditions of health must be established. Much can be offered by the orthopedic surgeon along the lines of physical reconstruction by team work and cooperation by physician, surgeon and orthopedist. Physical education in the young, which is now being very much neglected, should be carried out along the lines of proper appreciation of the proper posture and its resulting efficiency.

The Toxicity of Emetine.—R. N. Chopra, B. N. Ghosh, and Premanker De (*Indian Medical Gazette,* July, 1924) tabulate the results obtained by injection of emetine hydrochloride in rabbits and present the following conclusions: Emetine is a general protoplasmic poison having a selective action on the cells of certain organs in the rabbit. The parenchyma of the heart muscle is one of the earliest to be affected, the changes being cloudy swelling of the muscle fibres and disappearance of transverse striation; shrinking of the muscle fibres; atrophy of fibres and their replacement by connective tissue cells. These may be the cause of some of the cardiac symptoms which occur in the course of injections in patients. The presence of petechial hemorrhage at the site of injection and in other organs shows that emetine has a selective action on the endothelium of the capillaries. The liver and kidneys are also affected later, the changes being chiefly congestion and fatty infiltration of the parenchyma. A smaller number of injections are required to cure the disease if these are combined with large doses of bismuth subnitrate or carbonate by the mouth.

Posology of Beverages.—P. L. Violle (*Lancet,* May 17, 1924), as a result of his fractional diuresis test, asserts that in cardiovascular affections beverages should be taken with the patient reclining, and preferably on awakening in the morning and on retiring for the night. As far as possible drinks should be taken in small quantities at a time and not during meals. In a general way beverages should be reduced in proportion to the degree of cardiac insufficiency present, or, in other words, in proportion to the difference between orthostatic and clinostatic elimination. In delayed absorption from the digestive tract from gastric dilatation, beverages should be taken a long time after meals in divided doses, the patient in the recumbent position. In intestinal affections, such as profuse diarrhea, beverages need not be reduced, but should be given in such amounts as to bring the total quantity of urine as near normal as possible for twenty-four hours. In pathological portal hypertension, especially hepatic, the quantity of fluids which produce most abundant elimination should be determined by trial. In humoral disturbances, especially in retention due to chlorides, salt should be eliminated from the food and beverages should be adjusted to the reduced and uniform elimination.

THE PELTON & CRANE CO., DETROIT, MICH.

Restoring Intestinal Function

When the bowels cease to function and constipation develops, treatment, to give more than passing relief, must be able to restore normal intestinal function.

In selecting a therapeutic agent for this purpose, the practitioner will derive exceptional satisfaction from

AGAROL

since it is the one remedy available today that produces its effects by duplicating the action of the normally functioning bowel. *First,* it reproduces physiologic conditions within the bowel—softening the feces, increasing their bulk, and facilitating their passage—just as the intesinal secretions do in a state of health. *Next,* it furnishes the natural stimuli to peristalsis; and, *finally,* by the foregoing, the bowels are trained to regular action, and gradually brought to where they will continue to act naturally, without any further aid or assistance.

In action and effect, therefore, Agarol has shown that it is not merely a laxative or cathartic, but a true physiologic corrective of intestinal functions.

AGAROL is the *original* Mineral Oil-Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances—Not habit forming.

Early and Rapidly Progressive Lead Poisoning in Lead Paint Factories.—F. Heim, E. Agasse-Lafont, and A. Feil (*Bulletin de l'Académie de médecine,* July 22, 1924) call attention to the rapidity with which toxic lead manifestations may appear among workers in lead paint factories when inadequate protective precautions are taken. Within a few days after initial exposure to the lead many workers showed the lead line on the gums, basophilic degeneration of the red cells, or lead colic, parotitis, etc. Even though the workers left the factory within a few days or months, the risk of severe after results was not eliminated, one case, for example, developing a subacute and rapidly fatal pernicious anemia after having worked in lead for the first time for a few weeks only. Aside from insistence upon the customary precautions, which the workers are too often prone to neglect, clinical and laboratory examinations are of great value, especially a systematic examination of the blood of all the workers, preferably repeated at intervals of a few weeks or months in the men who are just entering upon the occupation entailing exposure to lead. This not only affords information of the average amount of lead intoxication prevailing among a body of workers but also detects promptly individual workers who, owing to neglect of precautions or unusual sensitiveness, are threatened with serious consequences unless they give up this form of occupation.

Aviation and Medicine.—At a meeting of the Royal Aeronautical Society on Thursday, March 5th, Lieutenant Colonel C. B. Heald, medical adviser to the Department of Civil Aviation, delivered a lecture on Some Medical Aspects of Air Transport. He pointed out that the medical questions of aviation were of interest not only to those directly concerned with flying—pilots, insurance companies, and the air traveling public, and to the whole medical profession—but to physicists generally; for in aviation, he said, we are dealing for the first time, so far as the history of mankind reveals, with life and work in three dimensions, and we are learning previously unknown facts about the mental and physical makeup of people subjected to strain and stress in a new environment. The medical work of civil aviation is not confined to the routine examination of pilots, although this naturally forms an important part of such work, but it has to take into consideration all matters concerning the general life of those associated with civil air transport, and all the general questions of hygiene and health organization that help to build up comfortable and efficient services. Colonel Heald gave a detailed description, illustrated by lantern slides, of tests employed on the medical examination of the pilot, and dealt at some length with the more general aspects of the career of the airman and the factors which influence his health and lasting powers. From these considerations some important facts emerge, showing that the estimation of complete fitness in flying men has given to clinical medicine a new viewpoint. And at this point the lecturer concluded that the measurement of physical conditions, as distinct from the detection of disease, demands a new technic, when results of a value as yet unreckoned may be clear. Colonel Heald believes that this new technic for estimating physical efficiency —in what manner each system of a particular individual will endure and function under stress and strain for that individual—will come, directly or indirectly, from our improving knowledge of electrical phenomena and the ultimate composition of matter, the outstanding features in the progress of medicine today being chiefly electrical. Colonel Heald's prophetic vision will not be dismissed as a baseless flight of fancy because a recent demonstration before two sections of the Royal Society of Medicine made clear only one thing—namely, that the subject was unready yet to leave the physical laboratory. Medicine, grappling with the problem of deciding the fitness of a man to adapt himself to a new element, has found that the criterions of health may not lie wholly in the stethoscope and sphygmomanometer, and Colonel Heald is logical when he says: "It would surely, therefore, be fitting if through this new science of aviation we should find our feet set on a new pathway, leading possibly to a definite understanding of those forces that Sir Oliver Lodge, Professor Richet, and the late Sir James Mackenzie have already sensed."—(*Lancet,* March 14, 1925.)

The Cancer Producing Factor in Tar.—E. L. Kennaway (*British Medical Journal,* March 29, 1924) states that the attempts made as yet to find the cancer producing substance among the known constituents of coal tar have given wholly negative results. Anthracene, phenanthrene, chrysene, picene, retene, truxene, acenaphthene, fluorene, acridine, carbazole, aniline, benzene, toluene, and xylene have been excluded by experimental tests; and either the experimental or industrial evidence, or both of these, is against the importance of naphthalene, the acids, bases, and other nitrogenous compounds, paraffins, olefines, and naphthenes. It now seems not unlikely that this substance is a compound, as yet unknown, which is unstable and present in amounts perhaps as small as those of the vitamines in foods; as is the case of some hormones, its identification may be long delayed even when very concentrated preparations can be obtained. The substances which are known to be present in coal tar have been isolated because they are specially abundant, or stable, or capable of forming well defined compounds; the unknown substances are unknown because they have not these properties, and the cancer producing substance may well be among them.

Reduce Fire Hazards by Removing Old Inflammable X Ray Films.—The Surgeon General of the United States Public Health Service has issued general instructions to remove from the clinical record files as many of the used x ray films of inflammable type as are not essential for record purposes. The storing of nitrocellulose films, especially when filed as a part of the clinical records, is, of course, well known to be a serious fire hazard and in conflict with the fire regulations of most cities. Boards of medical officers have been called in the various Marine Hospitals for the purpose. One of the larger institutions has eliminated approximately six hundred pounds of the old style used films from its records. The material has a small sales value. The use of fire resisting films which are not more inflammable than ordinary paper, and the storage of which, therefore, presents no special problem, was introduced in all Marine Hospitals on July 1, 1924.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Study of Child Labor.—The New York State Industrial Commission announces that a study of 412 working boys and girls under sixteen years of age, in New York city, conducted at continuation schools, showed nearly half with physical defects. The defects for each child averaged 2.4. Almost one-fifth of the children had visual defects, tuberculosis was found in one per cent., and four per cent. had heart affections. Half of the children worked forty-four hours, and six per cent. contrary to law, worked more than forty-eight hours. One third of the boys had work requiring them to be on their feet the entire day, and one quarter of the girls sat during the entire day. One fourth of the children were provided with wholly inadequate chairs.

Birth Rate in Germany.—Dr. Simon and Dr. Lucht of the Prussian Bureau of Statistics have been studying the birth rate of Germany. In Prussia the downward trend, noticed since 1909, was accelerated during the war, and is now only 50 per cent. of the pre-war rate. However, the tendency has been for an increase in the proportion of male births. While up to 1914, the highest ratio was 106.38-100, since the war the ratio has risen to 108.03-100. Prussia has the highest percentage of male births. In Denmark, Switzerland, and Holland, the percentage of male births has not changed much since the war.

Fire Danger at State Institutions.—Considerable anxiety is felt over the fire hazards at the various municipal hospitals and institutions for care of children and the aged. Especially dangerous are the wooden buildings of the City Home, where over two thousand old and feeble men and women are cared for, many of whom without assistance, would be utterly unable to escape from fire. Many buildings are in such a condition that it would take disproportionate sums to repair them, and they should be replaced with new structures. In spite of endorsements by the State Charities Aid Association and other interested organizations, of the $1,500,000 asked for by Commissioner Coler for the elimination of fire hazards this year, only $200,000 was granted.

Large Drug Shipment to Greece.—Probably the largest drug shipment ever to leave an American port, consisting of fourteen million five grain quinine tablets, is on its way to Greece, where it will be used to combat the scourge of malaria existing in the refugee camps of that country. The repatriation of nearly 1,000,000 Greek nationals from Asia Minor unavoidably resulted in many of these being quartered in malaria country. The result was a scourge as dreaded as that of typhus. The liberal distribution of the quinine shipments of the American Red Cross has, according to the Greek Department of Hygiene, saved the lives of tens of thousands of the refugees and enabled countless others, who otherwise would have been unable to work, to reestablish themselves in their new homes.

Rearrangement of State Health Districts—A rearrangement of the districts of four District State Health Officers, involving a shift of three counties of New York nas become effective. Dr. E. R. Richie, Brewster, takes over Columbia County, formerly in the district of Dr. Huntington Williams, Albany. Westchester, formerly in Dr. Richie's district, goes to Dr. Richard Slee, who is stationed for the present at Rockville Centre, Long Island. Rockland County is transferred from Dr. Slee's district to that of Dr. Frank Laidlaw, Middletown. From September 1st the four districts will be composed as follows: Dr. Williams, Albany, Renssalaer, Green, and Schoharie. Dr. Richie, Columbia, Dutchess, and Putnam. Dr. Laidlaw, Ulster, Sullivan, Orange, and Rockland. Dr. Slee, Westchester, Nassau, and Suffolk.

Wilmer Foundation.—An announcement has been made that the three million dollar endowment fund had been completed for the Wilmer Institute, devoted to teaching research, and hospital care, in connection with Johns Hopkins University. The money (with the exception of one million from the General Education Board) has largely been raised by friends and patients of Dr. William Holland Wilmer, of Washington, and it will enable him to devote his time to research on diseases of the eye. Mrs. Aida de Acots Root of New York, whose eyesight Doctor Wilmer saved, learned that he had himself paid a deficit of $6,000 in the operation of his hospital, and started to raise sufficient money to enable him to devote at least part of his time to research. Johns Hopkins University has assigned to the Institute a building and land valued at $200,000.

Miscellany.

The Anatomy of Twins.—Twin bodies of the uniovular type do not often come to the anatomist for examination. Hence not much is known with certainty or conclusive definiteness about the relations existing between the twins of this form, and the views advanced from time to time about the cause of twinning are little more than assumptions adopted to fill the void of ignorance on the subject. The theory of polyspermy as a cause is an example of such assumption; it is probably quite unsound and untenable from the nuclear and cytological point of view, and it can be pointed out that, in animals in which polyspermy normally or frequently occurs, the additional spermatozoa are noneffective to all appearance, while in a case like that of the armadillo, in which normally more than one embryo is formed from a single ovum, there does not seem to be polyspermy. All that can be said with certainty is that the uniovular twin is an end product of the process of dichotomy affecting the embryonic contents of the developing ovum, and the cause of its occurrence will be known when the explanation and meaning of dichotomy is understood. The result of dichotomy may be incomplete or complete division, and, in its axial form, ranges from the parasitic fetus and other monstrosities, through the partially attached individuals to the completely separated twins. In this last case the embryonic division may stop at this point, leaving the amnion undivided, or may even involve this, so that each individual possesses his or her own amnion. It is theoretically conceivable that the dichotomous process, beginning at the earliest possible moment, might lead to complete division of the whole ovum, so that each fetus would have its own chorion and placenta; but the occurrence of such a condition has never suggested itself to any observer, and a single chorion and placenta may thus be considered a proper accompaniment of uniovular twins. This, in fact, seems to be the most valuable criterion, in practice, in deciding on the nature of twin births. Those of opposite sex are not uniovular; when of the same sex they may or may not be so, but when they are enclosed in a common chorion, or—the same thing—have a common placenta, they are uniovular. When such details as these are lacking in the birth history, it is not possible to give more than the negative pronouncement that twins of different sex are not uniovular.—*Lancet,* March 14, 1925.

French Medicine and Louis Pasteur.—A lecture on the great discoveries of French medicine was recently delivered at the Institut Francais du Royaume Uni in South Kensington by Dr. Cruchet, professor of the Faculty of Medicine, Bordeaux. Passing in review the history of the ancient University of Montpellier and the many illustrious physicians whom it had produced, he recalled the career of Rabelais who studied there under Rondeletius. And then coming to the time of Louis XIV and the physicians satirized by Molière, while claiming that even among them there were some great Frenchmen, he acknowledged that their work was eclipsed by that of Harvey and Sydenham, to whom he paid fitting tribute. In Dr. Cruchet's opinion the greatest of all medical men was Laënnec, whose *Treatise on Auscultation* was given to the world in 1819. It always appears strange to us to hear a Frenchman depreciate the achievements of Pasteur, when comparing them with the work of his compatriots. Like others we remember, Dr. Cruchet acknowledged him as a genius, but from the point of view of pure medicine he placed the great French physicians of the nineteenth century on a higher plane. It seems to be becoming the custom to labor the fact, denied by none, that the germ theory was no new idea, and to quote from earlier works what each critic is pleased to consider a prior conception of the microbial origin of disease. It is very well to produce passages from the works of Fracastorius, from Edward Maynwaring and other obscure seventeenth century philosophers, from Haighton the gynecologist and other forgotten authors, as Dr. Cruchet did, from the *Etude sur le virus of Jean Hameau,* published in 1836, which the lecturer considered superior "from the point of view of pure medicine," to the works of Pasteur. Which of these men, whatever his philosophical lucubrations, brought pure medicine even a foot's breadth nearer to the light? It remained for Pasteur to demonstrate the theory which had been suggested by others. He was a chemist, and as a chemist he demonstrated the secret of fermentation, and afterwards applied it to disease. *"Si j'avais l'honneur d'être chirurgien,"* he said; as if he had not done enough. In our conception, the genius of Louis Pasteur stands alone; and with profound admiration for his industry, his insight and his intellect, we shall continue to regard him as the greatest scientist of all time.—*Medical Press and Circular,* March 4, 1925.

Vital Statistics for 1924.—The Department of Commerce announces that birth rates for 1924 were higher than for 1923 in sixteen of twenty-five states in the registration area. The highest 1924 birth rate (31.9 in 1,000 of population) is shown for rural districts of North Carolina and the lowest (14.9) is for rural districts of Montana.

Death rates for 1924 were lower than for 1923 in twenty-three of twenty-nine states. In fact, record low rates appear for the following thirteen States: Connecticut, Delaware, Kansas, Kentucky, Maine, Massachusetts, Montana, Nebraska, Ohio, Pennsylvania, Vermont, Virginia and Wisconsin. The six States having higher rates for 1924 than for 1923 are: California, Florida, Mississippi, Oregon, South Carolina and Washington. The highest 1924 death rate (22.1 in 1,000 of population) is shown for the urban districts of Mississippi and the lowest (6.5) for the rural districts of Montana.

Infant mortality rates for 1924 are generally lower than those for 1923, as only three of the twenty-five states show higher rates in 1924. The highest 1924 infant mortality rate (121.6) appears for the urban districts of South Carolina and the lowest (51) for the rural districts of Nebraska. Infant mortality rates are shown for both years for forty-four cities of 100,000 population or more in 1920. For thirty-six of these cities the 1924 infant mortality rates are lower than those of the previous year. The highest 1924 rate (92) is for Trenton and the lowest (45.3) for Seattle.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

IN CHRONIC CONSTIPATION

the bowel contents are abnormally retained in the intestinal canal. As a result, over-digestion takes place, with over-absorption of fluids from the fecal mass, leaving them hardened and reduced in bulk. In this condition the bowel contents, failing to provide the normal stimulus to the intestinal muscles, are still further delayed in their passage, thus preventing the elimination of toxic wastes.

In AGAROL COMP.—a palatable preparation of pure mineral oil, agar-agar and phenolphthalein—the practitioner has at his service a true bowel corrective. Administered in proper doses, it mixes thoroughly with the feces, making them soft, plastic and increased in bulk. In this condition they furnish the natural stimulus to peristalsis, and this, with their incidental lubrication, assures their ready passage.

Used over a reasonable period, therefore, Agarol Comp. restores the muscular tone and functional activity of the bowel, with the gratifying assurance that natural evacuations will follow regularly without the need for any further medication.

AGAROL is the *original* Mineral Oil-Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances—Not habit forming.

American Anthropologist Tracking Ancient Man.—A six months' search for the remains of primitive man on four continents has been begun by Dr. Ales Hrdlicka, curator of physical anthropology of the U. S. National Museum, now en route to Europe. He will also visit India from which, in the Siwalik hills, specimens of anthropoid apes with manlike characteristics have recently been reported. Straits settlements caves that have been inadequately explored will be visited by Dr. Hrdlicka and the sites of the discovery of the oldest man in the world, Pithecanthropus erectus, will be the reason for his trip to the island of Java. Skeleton collections of primitive aborigines will be examined in Australia and in Africa the site of the discovery of the mysterious Rhodesian skull will be visited. Dr. Hrdlicka will also confer with Prof. Raymond A. Dart, of Johannesburg, who recently found the Taungs skull, believed to be a man-ape and a precursor of man himself. On his expedition Dr. Hrdlicka will represent the Buffalo Society of Natural History as well as the Smithsonian Institution.

The First Book in English on Dentistry.—In 1686 Charles Allen, about whom the *Dictionary of National Biography* is silent, brought out in Dublin a book of fifty-eight pages, *The Operator for the Teeth, showing how to Preserve the Teeth and Gums from all Accidents as also the Description and Use of the Polican;* the only known copy is in the library of Trinity College, Dublin. In the following year, 1687, there appeared a second edition or reprint with an altered title, *Curious Observations in that difficult part of Chirurgery relating to the Teeth, shewing How to Preserve the Teeth and Gums from all Accidents they are subject to* [*Curious Observations on the Teeth.* By Charles Allen. The first known book on dentistry in the English language, 1687. London: John Bale, Sons, and Danielsson, Ltd. 1924.] ; seven copies are known to be extant, and from that in the British Museum (782, 1.5 (1)) a reprint has been made. Allen considered that he was the first to write on the subject, and Miss Lilian Lindsay, who contributes an introduction, remarks that Berdmore, nearly a century later, made a similar statement, and that the value of Allen's book is not so much its priority or its contents as that it is one of the rare examples of Dublin printing in the seventeenth century—probably one of the most disastrous that even distressed Ireland has ever experienced—when the hearts of writers and printers alike failed them for fear to publish. The surviving part of his teaching is the importance to be attached to the care of the teeth in early life, which is "conducive to the preservation of life and health of children . . . and to the preventing of all those infirmities wherewith they are afflicted." It is dedicated "To the most Honourable and Truly Learned The Physitians, Chirurgiens, and Apothecaries of the City of Dublin," and on the next page, under the original title "The Operator for the Teeth," has a proem beginning with the laudable and disarming sentiment, "Knowing that it is the duty of every man, and especially of such as live under a Civil Government, (where the general Interest always includes the particular) to contribute as much as he can (in his own station) to the publick Good." The work contains seven sections, dealing with: the Nature of the teeth; the alterations of the teeth, with their remedies; the corruption of the teeth, with their remedies, whereto is annexed the description and use of the polican; the restauration of the teeth; the toothake, looseness of the teeth, and decay of the gums, with their remedies; children's teeth; and the "acceleration of the teeth," which gives instructions how to hasten the growth of children's second teeth and also "those in men that are called the teeth of wisdom."—*British Medical Journal,* February 21, 1925.

Refraction of X Rays.—An accurate measurement of the refraction of x rays has recently been made by Professor Bergen Davis and his coworkers at Columbia University. The bending of the rays at the surface of matter is very small, but by proper refinements of apparatus it can be measured quite accurately. These measurements permit the computation of the number of electrons in the inner level of an atom. The number found is two, in agreement with the Bohr scheme of atomic structure. The possible refraction of x rays was indicated by the experiments of Stenstrom a few years ago. Recently Professor Manne Siegbahn, of Upsala, Sweden, succeeded in showing this refraction directly by the bending of the rays in passing through a glass prism.

Eugenic Marriage Laws.—In 1913 the State of Wisconsin passed a Eugenic Marriage Law, requiring every man who applied for a marriage license to provide a physician's certificate attesting his freedom from acquired venereal disease. Since then six States have followed the example, but thirty-seven others have rejected similar proposals. It has been assumed that their refusal is based upon the conclusion that the law fails to attain its purpose, but on the other hand, it may well be that as in this country, the restriction of marriage is viewed with disfavor, as too great an interference with the liberty of the subject. An investigation into the operation of the law of Wisconsin, founded upon information by questionnaire, has recently been published, from which it appears that the original Act did not require the Wassermann test. Two years later provision was made for free laboratory service by the State, requiring clinical and other tests when the examining physicians deemed them to be necessary. It appears that in spite of quite inadequate remuneration—the fee is fixed at two dollars—the examination is conducted in a regular and conscientious manner, although about one fourth of the physicians, practising within the State, report that they do not always perform physical examination, relying upon their personal acquaintance with the applicant. A two thirds majority was of opinion that the law is valuable in preventing the infection of brides, but many adverse criticisms were levelled against it. Among these it was argued that women are not examined, that infection is not prevented by the forbidding of marriage, that marriages prescribed in Wisconsin are celebrated in some other State, and that, in the absence of the requirement of laboratory tests in every case, the security against infection is false and incomplete. But however well founded these objections may be, the fact remains that the balance of opinion is in favor of the law and the restrictions it entails.—*Medical Press and Circular,* March 4, 1925.

Simpler Beds Urged for Hospitals.—Hospital beds, about the simplest form of sleeping equipment made, have been further simplified through the efforts of the U. S. Department of Commerce. They are now made in thirty-three different lengths, thirty-four different widths and forty-four heights. Following a conference with hospital officials, the government recommends that the standard hospital bed should be seventy-eight inches long and thirty-six inches wide, with widths of thirty-three and thirty-nine inches when narrower or wider beds are necessary. A bed twenty-seven inches high is said to be the most convenient for nurses. The government and forty-six hospitals, manufacturers and associations have adopted this size as standard.

The American Hospital Association estimates that more than $350,000,000 is spent annually for new construction and equipment in the hospitals of the United States and Canada. The Department of Commerce says that a saving of only one per cent. by reducing the waste due to excessive variety in hospital equipment would mean the release of nearly $10,000,000 a year that could be expended for enlarging hospital facilities.

Dr. Burr Says Dickens's Characters Art Not Scientifically Accurate.—The numerous queer characters who populate the pages of Charles Dickens's books are correctly depicted from the viewpoint of the layman, who sees what he thinks he ought to see, but not when viewed by a specialist in mental diseases. This is the opinion of Dr. Charles W. Burr, professor of psychiatry in the University of Pennsylvania Medical School, who has applied to these fiction characters the methods which he uses in diagnosing mental disorders when called into a criminal court as an alienist.

"Dickens was an artist," says Dr. Burr, "and not a specialist in mental medicine. Just as the dying of a great actor on the stage is altogether unlike death as the physician sees it, so life seen with an artist's eyes is unlike life seen by the professor trained in the learning of the schools. Death as it really happens acted on the stage, would be flat, stale and uninteresting. Dickens describes a fairyland, not seldom a fairyland into which devils have intruded. This is the secret of his wide appeal spreading through space and lasting through time."

"Dickens was himself queer, at least in his early life; his father and mother were both impractical persons, but," says Dr. Burr, "many, if not all, the men who have done great things have been queer little boys."

"Sticklers for scientific accuracy criticize him adversely and say that no man of science could classify, that is, pigeonhole, Miss Flite, Miss Havisham and Krook. These men of the professional mind are, to say the least, a trifle hasty. There is a wide borderland in the world of mental life, whose inhabitants are neither sane nor insane, their thoughts are ruled by laws we know not of, they cannot be classified, and so different are the types that almost any combination healthy man can conceive may be met there. We men of science try to classify them and they call them paranoids, mattoids and many other names, but the country is a jungle full of strange animals still unclassified."

Valentine's Meat-Juice

For **Quieting** the **Irritable Stomach** in **Pregnancy**, for **Rapidly Restoring** the **Vital Forces** in **Hemorrhage**, for **Sustaining** and **Strengthening** in **Long** and **Exhausting Labor**, **Valentine's Meat-Juice** is extensively employed in

Obstetrical Practice.

VALENTINE'S
PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Dr. E. Duloroy, *Physician Accoucher to the International Hospital, Paris, France:* "A young accouchée, in a very weak condition and suffering from stomach trouble, could retain no food, but was able to assimilate VALENTINE'S MEAT-JUICE given at first in small doses. An improvement was quickly visible, the patient recovered her strength and is today in good health."

Dr. Javier Ortis y Ferrer, *Physician to the Municipal Charity of Madrid, Spain:* "VALENTINE'S MEAT-JUICE has given the happiest results in cases of debility and in the asthenia produced by operations of confinements. In some cases of Tuberculosis it restored exhausted strength, and in every case where organic exhaustion manifested itself as an effect of disease."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

Miscellany.

Metabolism Studies with Chaulmoogra Oil.—Bernard E. Read (*Journal of Biological Chemistry,* December, 1924) says that in view of the benefit obtained in the treatment of leprosy by the use of both codliver oil and chaulmoogra oil, it was thought that the latter oil might have an action similar to codliver oil upon general metabolism. The present investigation was undertaken to study the influence of chaulmoogra oil upon calcium metabolism. A marked increase in urinary calcium was produced in rabbits by the administration of large doses of chaulmoogra oil or ethyl hydnocarpate. Dogs given small doses orally showed a marked increase in urinary calcium, and an increase in fecal calcium. Continued administration reverses this effect, and favors calcium retention. Prolonged hypodermic administration of ethyl hydnocarpate in therapeutic doses to dogs decreases the urinary calcium and favors calcium retention. Large intraperitoneal injections decrease the urinary calcium and greatly increase fecal calcium so that there is a hyperexcretion of calcium. The blood calcium showed an increase after administration of the hydnocarpates to dogs; large doses producing a fatal effect in rabbits cause a decrease in blood calcium with tetany. The chemical analyses made show that there is the development of a tolerance to the original effect of the drug upon metabolism, particularly as seen in the lessened local irritant effect upon the alimentary canal.

The Resistance of the Brain to Disease.—It often happens that a person full of years and wisdom, his brain at the very acme of its powers, succumbs to a disease which leaves that organ intact to the end, says the editor of the *Medical Press and Circular,* April 29, 1925. He goes on to say that when the life of a brain endowed with rare powers, amplified and strengthened by long years of strenuous endeavor, is suddenly brought to an end in the plenitude of those powers and through no weakness of its own, but as the result of disease in some other part of the body politic, the event is one calculated to make the thoughtful ponder on the mystery of things. Such cases are peculiarly tragic, the more so when the victim is a person of outstanding ability.

Two eminent men have recently died in the full possession of rare gifts—the one supreme in statecraft, the other supreme in art. Consider the case of Mr. Sargent. Here was a man whose work showed no falling off from its customary high standard. Up to the very moment of his death his hand posesssed that subtle trick of manipulating brush and pencil of which he alone held the secret: the heart ceases to beat, blood ceases to flow in the brain, and although for a brief spell some show of life persists in individual neurons, that neuronic interplay which is associated with mental activity is brought to a standstill: the vastly complex cerebral integrate is instantaneously broken up, and the mental personality, so far at least as its mundane existence is concerned, vanishes.

It would appear that this great artist succumbed to chronic Bright's disease and the associated cardiovascular complications. The cardiac hypertrophy, without attendant valvular disease, indicated a long standing augmentation of systemic peripheral resistance and consequent heightened blood pressure, all of which were the direct or indirect outcome of a morbid blood plasma.

A remarkable feature of cases such as this is that while the morbid blood plasma induces widespread degeneration, the cerebral neurons, of all cells the most highly organized and sensitive, are often surprisingly free from disease, so that the patient remains in full possession of his faculties.

This exemption is to be explained by the fact that in virtue of their importance, special precautions are taken by the organism to protect them from the nocuous influence of a toxic plasma. Between the blood plasma flowing in the cerebral capillaries and the cerebral neurons a special protective mechanism appears to have been placed for the purpose of intercepting the passage of nocuous substances into the perineuronic lymph spaces. We seem to have evidence of the existence of such a mechanism in the fact that compounds of arsenic and mercury circulating in the blood are for the most part prevented from entering those spaces, although they gain ready entrance to the plasma surrounding the nerve fibres of nerve trunks.

It is manifest that the protection thus afforded even if it exists at all, is far from perfect, for otherwise the brain would not react to toxins circulating in the blood.

Noncalculous Intermittent Biliary Obstruction.—E. S. Judd and V. G. Burden (*Annals of Surgery,* April, 1924) present twenty-four cases, of which they say that there seemed to be a little doubt that intermittent biliary obstruction was the main cause of symptoms. Stone in the common duct was suspected, but not found at operation. It is not generally recognized that the pancreas can be responsible for intermittent biliary obstruction. Intermittent obstruction at the outlet of the bladder can be caused by infection in the prostate, while obstruction, more or less permanent in character, results from hypertrophy or malignancy. The swollen, edematous gland of pancreatic lymphangitis, the type associated with cholecystitis, might in a similar manner cause intermittent biliary obstruction, colic, and even jaundice. The normal gallbladder functions as a tension bulb in the presence of common duct obstruction as in cases of carcinoma of the pancreas. After removal of the gallbladder any sudden obstruction to the common duct causes rapid distention of the proximal ducts with resulting pain. If the elasticity of the gallbladder has been destroyed by disease, or if it has been removed, pancreatitis may be the cause of biliary obstruction, severe colic and jaundice. This is probably the explanation of events in some cases of cholecystitis without stones, in which severe colic and jaundice have occurred. After reviewing the histories of these patients, the authors are convinced that an accurate diagnosis cannot always be made. The symptoms are those of intermittent biliary obstruction, the usual cause of which is stone in the common duct. The surgeon should not be disappointed if he occasionally fails to find a stone. Drainage of the ducts will relieve the symptoms in most cases.

PELTON

Indestructible Sterilizers

THE PELTON & CRANE CO., DETROIT, MICH.

Restores Natural Bowel Action

Among the many remedies for constipation, bowel torpor, intestinal stasis or any form of dyschezia of functional origin, there is hardly one that has met with such instant approbation and acceptance by discriminating physicians as

AGAROL

A reasonable test of this scientifically balanced combination of pure mineral oil, agar-agar and phenolphthalein in some severe case of constipation will enable the practitioner to understand why Agarol is winning the regard and confidence of a constantly increasing number of medical men. He will find that Agarol

1st—*produces* prompt and satisfying bowel evacuations;
2nd—*increases* the bulk, softness and plasticity of the fecal mass;
3rd—*imparts* functional tone and power to the intestinal muscles;
4th—*restores* functional activity of the bowels so that satisfactory evacuations will follow regularly and continue without the need of further medication.

Agarol is not only a palliative of intestinal torpor—it is a true bowel corrective.

Manufacturing Pharmaceutists Since 1856

The Ship Surgeon's Chest.—A revised list of the medical stores which merchant ships will be required to carry after June next has just been revised by the Board of Trade. The drugs included in it have been selected by the Colleges of Physicians and surgeons and the Pharmaceutical Society—we seem to miss the Society of Apothecaries. Among those which must be carried on all ships having one hundred or more passengers, thereby entailing a ship's surgeon, are several which have been added since the last list was issued about twelve years ago, such as adrenalin, emetine, pituitary extract, hexamine and salol. There must also be sufficient sterilized dressings for one major operation. It is not so long ago since a Cox's key was among the instruments required. Though a relic of barbaric times, it was a most useful weapon, supplying the place of a whole armory of dental forceps, and in experienced hands capable of forceful, though far from painless, results. In those days tincture of arnica, a drug almost unknown to present allopathic pharmacy, was the panacea for sprains and contusions. Iodine was only used as a counterirritant—indeed, until quite recent years, it was never applied except to the unbroken skin.—*Medical Press and Circular,* March 11, 1925.

Effects of High Environmental Temperatures on the Organism.—Frederick B. Flinn, associate physiologist, office of Industrial Hygiene and Sanitation, United States Health Service, recently undertook research work for the purpose of obtaining a more intimate knowledge of the specific effects of high environmental temperature upon the individual organs and tissues of the body so that the more general effects as observed among men who are compelled to work where the air temperature is abnormally high could be more intelligently interpreted than has heretofore been possible. The following is a summary of his findings, which are published in *Public Health Reports,* May 1, 1925:

During an exposure of six hours to an environmental temperature of 20° or 30° C. there was a drop in body temperature, probably due to a decrease in muscular activity. At 40° there was an increase of one degree in body temperature without an initial drop. At 45° and at 50° the body temperature rose within an hour to such a height that it was deemed unsafe to continue the experiments.

The oxygen capacity of the blood showed no changes during the exposure to the different temperatures that can not be accounted for by the diurnal changes in the hemoglobin or the concentration of the blood due to excessive evaporation of water.

The oxygen content of the blood remained unchanged at 20°, but showed a drop at 30°, which is probably associated with the low rate of metabolism at this temperature. At 45° and 50° there is a slight increase in the oxygen content, due to the increased aeration of the blood at these temperatures; but this increase is not in direct proportion to the increased passage of air over membranes of mouth and throat.

At temperatures of 20° and 30° the alkali reserve remains unchanged, while at 40° there is a sharp fall during the first four hours, followed by a slower fall during the next two hours. At temperatures of 45° and 50° there is a rapid depletion of the alkali reserve from the beginning, which is almost identical for each of these two temperatures.

The carbon dioxide content follows the alkali reserve, except that at 30° there is a slight rise for the same reason that at the oxygen content falls.

The hydrogen ion concentration of the plasma remains unchanged during an exposure of the animal to a temperature of 20°, 30°, and 40°, but decreases at temperatures of 45° and 50°, due to the excessive pulmonary ventilation at those temperatures with the consequent washing out of carbon dioxide without a compensatory loss of alkali from the blood.

The concentration of blood sugar falls during an exposure to temperatures of 20° and 30°. This fall is probably associated with inactivity of the animal during the course of the experiment. At 40° it falls during the first two hours to increase during the following four hours. At 45° no change was noted during an hour's exposure, while at 50° there was a sharp rise during this time.

The blood solids at 20° and 30° showed only the usual diurnal changes. At 40°, 45°, and 50° the concentration of the blood increases with the environmental temperature, no initial drop being seen.

An increased air movement benefits the organism by delaying the deleterious effects, but apparently at the expense of the organism itself.

The free drinking of water during an exposure to high air temperature is of greatest benefit in maintaining the organism in a normal condition.

Abnormality Among Texas Criminals Abnormal.—Less than one third of the prisoners in the Texas penitentiary are mentally normal, and only eleven per cent. are free from obvious physical disease or defect. These facts are reported by the National Committee for Mental Hygiene following a survey of conditions in the penal institutions of Texas made at the request of the state. The committee urges a medical and psychiatric clinic for study and treatment of offenders, and better hospital facilities and a training school. It also urges that prisoners be given indeterminate sentences, so that they may be released when they are rehabilitated and are judged ready to become useful members of society.

"Psychiatry," says the committee, "does not subscribe to halfbaked theories of pseudoscientists, like those who recently ascribed all crime to socalled emotional insanity which has its seat in the brain, is inherited and incurable, and can only be prevented by sterilization. Neither does it subscribe to the maudlin sentimentality which would have no one locked up or punished. The psychiatrist does maintain that the mental and physical condition of the prisoner has a great deal to do with his conduct and that an effort must be made to understand his mind and personality before sound correctional treatment can be administered. Experts who have studied the penal situation believe that constructive criminology has reached such a knowledge of the criminal and his rehabilitation that we may safely and wisely make investments in buildings, apparatus, and personnel. Additional expense in the interests of crime prevention is true economy in the long run."

The committee's report says that the majority of the Texas prisoners are under thirty years of age and that much can be done to remold the personalities of young offenders into socially acceptable forms.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Breathing Capacity and Delinquency.—There is apparently an important connection between breathing capacity and delinquency among women. Recent investigations by Dr. Frederick L. Hoffman, consulting statistician of the Prudential Insurance Company of America, into the present day human physique, with a due regard to age, sex and race, has revealed among other interesting results the striking fact that normal women usually have a chest expansion about three centimetres greater than delinquents at corresponding ages. He says: "While delinquents apparently have a slightly better general physique than normal women, as indicated by a somewhat larger chest and abdominal circumference, their breathing power is distinctly less, and this vital inferiority may have an important bearing upon mental development, for otherwise physically delinquent women exceed rather than fall below the averages for the different bodily proportions as ascertained by painstaking measurements."

Dr. Hoffman's investigation included a larger number of individuals and has covered a considerable period. In normal women at thirty years of age the chest expansion averages 11.2 centimetres against 9.8 for delinquents. At ages beyond this, the difference is still more marked, being 10.2 for normal women and 7.6 for delinquents. Expressed in inches the differences are: Under thirty, the chest expansion is four and a half inches in normal women; four inches in delinquent women. Over thirty, the expansion is four inches in normal women; in delinquent women three inches.

Only in breathing capacity did the measurements disclose an inferiority among delinquents. Thus, says Dr. Hoffman, the abdomen, which is a fair index of nutrition, was eighty-eight centimetres circumference for normal women under thirty years, while for delinquent women it was ninety centimetres. Among normal women over thirty the abdominal circumference was ninety-four centimetres against ninety-three among delinquents. Average weight under thirty was 125 pounds for normal women and 130 for delinquents; over thirty the corresponding weights were 142 and 135 pounds.

The data from which he derived his findings and conclusions included more than four thousand measurements of both sexes of Caucasians, Negroes, Caribs and Indians of North, Central and South America. These measurements were all made under uniform methods either by himself or under his direction through the cooperation of health officers and physicians in charge of reformatories and correctional institutions.

Natural Science Courses in the Jungle.—Courses in the natural science of the tropics are to be carried on in the jungle during the coming summer by the University of Pittsburgh. The Tropical Research Station of the New York Zoological Society, at Kartabo, British Guiana, has been turned over to the university for several years. The main work will be carried on during the summer months, but a permanent custodian has been stationed at the laboratory, so that it will be available at any time. A group of fifteen students, under Professor S. H. Williams of the department of zoology, plans to leave in June.

New Publications Received.

When You Prescribe

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

and your prescription is filled by some cheap, worthless substitute which some druggists buy in bulk, your efforts are defeated and your patient's condition is jeopardized. You owe it to yourself as well as to your patients to make sure that they get

The Original "Gray's"

which has 35 years of faithful service to the medical profession as its guarantee of

1. Highest Quality of Its Ingredients
2. Painstaking Care and Skill in Its Compounding
3. Uniformity and Integrity of Character
4. Maximum Therapeutic Efficiency.

There is only one Gray's Glycerine Tonic Comp. Insure your results and safeguard your patients by writing your prescription as follows—

℞ Grays Glycerine Tonic Comp. (P. F. Co.)

Valentine's Meat-Juice

In **Typhoid, Gastric** and **Other Fevers,** where it is **Essential** to **Sustain** the **Patient** without **Irritating** the **Weakened Digestive Organs, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** of **Restoring** and **Strengthening** when **Other Food Fails.**

J. R. Wood, M. D., *Physician Sheltering Arms Hospital, Paint Creek, W. Va., U. S. A.:* "I have been using VALENTINE'S MEAT-JUICE in the treatment of Typhoid Fever cases in the Sheltering Arms Hospital, for the last two or three weeks, with the most gratifying results both to the patient and physician. I consider it the best preparation of animal food I have ever seen, in fact, the only one I have ever had any success with."

Dr. Genevaix, *Assistant Surgeon-Major, First Class, Hotel Dieu, Creusot, France:* "The patients to whom I have given the excellent preparation, VALENTINE'S MEAT-JUICE, have found their general condition rapidly improved by it, and in the convalescence from continued Fever (Typhoid and Para-Typhoid) it gives the best results."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

VALENTINE'S PREPARATION
NUTRIO PHARMIC
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Broadcasting Heart Sounds.—Under the supervision of Dr. R. Lutembacher, who is well known in Paris as a heart specialist, the beats of one healthy and six diseased hearts were recently broadcast from the Eiffel Tower station, says the *Lancet,* May 23, 1925. Dr. Lutembacher has hopes that in the future by this means a doctor may be enabled to follow the progress of a patient, though he does not suggest that a complete diagnosis of a case previously unseen would be possible. He declares that by the aid of an amplifier a patient's heart beats are clearly audible over an ordinary telephone. A further valuable feature of such experiments is that they may bring the country doctor and the hospital specialist into closer touch. This experiment is said to be the first of a series. Attempts on similar lines at Bristol and in Charlottenburg were recorded last year. Radio transmissions have since been carreid out on several occasions by the Welsh National School of Medicine from the British Broadcasting Company's station in Cardiff. On one occasion two cases with well marked cardiac bruits were correctly diagnosed by a medical man in Somerset. However, the aim of these transmissions was not so much to test the value of broadcasting heart sounds for the purpose of diagnosis of progress as to obtain information with regard to their magnification many hundreds of times by means of thermionic tubes. If a high degree of amplification without distortion is possible, then we have a new line of approach for investigating the nature of these sounds. It is possible that further light may be thrown upon the mechanism of their production or that vibrations hitherto undetected may be revealed. In exceptional circumstances the broadcasting of a patient's heart sounds might be of benefit, in that expert opinion not available at the bedside might be obtained from a distance. But it is probable that a short account of the patient's condition and symptoms would be more likely to bring help than the transmission of his heart sounds through the ether.

The Antimalarial Campaign in Ceylon.—Walter Peiris, L.R.C.P., (*World's Health,* April, 1925) says that malaria is prevalent in all parts of the island in varying degrees, and investigations with a view to eradicating the disease have been carried out for a number of years by an expert at the expense of the Government. Although malaria is not such a fatal disease as pneumonia, enteric, dysentery, influenza, phthisis, etc., its effects on the human system are so harmful that the high death rate of the island is thought to be, in some measure, attributable to it. A total of 23,326 deaths (11,608 males and 11,718 females) have been certified as being due to pyrexia. This certainly is an indication of the havoc caused by malaria. Further, the districts where the death rate from pyrexia is high are also reputed to be highly malarial, and where the death rate from pyrexia is low, the existence of malaria is said to be less pronounced. Pyrexia and malaria have jointly claimed as victims 5,600 persons out of every million of the estimated population. The number of persons killed by malaria and malarial cachexia in 1923—the latest year for which statistics are available—was 2,659, of whom 1,491 were males and 1,168 females as against 2,046 in 1922 and 1,796, the average for the decade 1913-22. This corresponds to a rate of 573 per million persons.

Ceylon is dependent on India for its food supply. In olden days, during the time of the Cingalese Kings, Ceylon was said to have produced sufficient rice to be able to export to other countries. There are thousands of acres that could be cultivated were it not for the malarial scourge. The seriousness of the problem from the point of view of the life and health of the citizen, and the importance of the question from an agricultural and economic point have induced the Government to appoint a Committee to control the malarial campaign which is to be carried out on an extended scale. The principal duties of the committee will be:

1. To receive reports from experts and advise upon these reports.
2. To consider the practical application of all suggested measures for the control of malaria as they may affect different sections.
3. To consider the best means of obtaining thorough cooperation from all sections of the community.
4. To consider the relative urgency and probable cost of proposed anti-malarial measures and submit estimates to the Government.

The campaign will be divided into four sections, viz., administrative, educational, medical and entomological, and it is understood that active control measures will be started simultaneously in several parts of the island.

X Ray Photographs Sent by Wire.—Quick x ray diagnoses by eminent specialists have been made possible by telephoning x ray photographs. A negative showing the bone structure of the human hand was sent from New York to Chicago in seven minutes on Wednesday, April 15th. Details were not lost in the procedure, and an accurate examination of the film was possible. "The time element in the diagnosis of an injury or ailment by a specialist is most important," said W. S. Kendrick, vice-president of the Victor X Ray Corporation of Chicago, following the reception of the first telegraphed x ray negative. "In complicated fractures or other bone injuries, a quick diagnosis is invariably desirable in order to prevent infection or other complications.

During the recent tornado in the Middle West, a woman received a severe fracture of the knee. The medical men available, who were not x ray specialists, were unable to treat her, and it was necessary to take her to New York. If an x ray film could have been sent by wire, a specialist would have been able to reply immediately with instructions for preventing permanent lameness or other complications without the necessity of going to New York. The possibility of sending the negatives by wire brings the specialist to the small community.

Dr. D. W. Coolidge, of the General Electric Company, has perfected a portable x ray equipment which a doctor can use anywhere by connecting it with the household lighting circuit. These widely used outfits have eliminated the necessity of moving a patient to a hospital for x ray examination, and now telephonic transmission of photographs indicates that soon it will not be necessary to take patients to large cities to secure the services of specialists.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Intestinal Stasis

as Lane has shown, is responsible for more diseases than any other one cause. Unfortunately, its correction presents many difficulties.

In AGAROL COMP., however, the practitioner has at his command, a unique combination of mineral oil, agar-agar and phenolphthalein, that not only will produce thorough elimination from the bowel without nausea, griping or distress, but also, when systematically employed, will restore the muscular tone and functional activity of the intestinal canal.

A constantly increasing number of medical men, therefore, are employing Agarol Comp. in the treatment of intestinal stasis, for they have found that its systematic use for a reasonable period means the permanent restoration of bowel function, after which it may be discontinued with the gratifying certainty that regular evacuations will follow without further assistance.

AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbance; not habit forming.

A generous supply for thoroughly testing Agarol Comp. will be sent on request.

Amendments to the State Sanitary Code.—At a meeting of the Public Health Council held in New York City on May 5, 1925, regulation 37 of Chapter II of the Sanitary Code was amended to take effect June 1, 1925, and to read as follows:

Regulation 37. Sale of food forbidden in certain cases. When a case of diphtheria, epidemic (lethargic) encephalitis, epidemic or septic sore throat, amoebic or bacillary dysentery, epidemic cerebrospinal meningitis, paratyphoid fever, scarlet fever, smallpox, poliomyelitis, acute anterior (infantile paralysis), or typhoid fever exists on any farm or dairy producing milk, cream, butter, cheese, or other foods likely to be consumed raw, no such food shall be sold or delivered from such farm or dairy, except under the following conditions:

1. That such foods are not brought into the house where such case exists;

2. That all persons coming in contact with such foods eat, sleep and work wholly outside such house;

3. That such persons do not come in contact in any way with such house or its inmates or contents;

4. That said inmates are properly isolated and separated from all other parts of said farm or dairy, and efficiently cared for; and

5. That a permit be issued by the health officer, or in his absence by the district state health officer.

Scandinavian Medical Literature.—Those to whom English is the native tongue are greatly interested and not a little gratified by the growth of the study of the English language in the three great Scandinavian countries, says the *British Medical Journal,* April 25, 1925. Sympathy with them is traditional in England, where in some parts is a strong strain of Scandinavian blood, evidenced by place names and also by the construction of the common surnames. The extent of the movement in Scandinavia is indicated by the existence of flourishing societies. The Anglo-Danish Society has its headquarters in Copenhagen, the Anglo-Swedish in Stockholm, with branches in the university towns Upsala and Lund; the Anglo-Norse, established in Oslo (Christiania) has branches in Stavanger and Bergen. These societies are large and growing, and the *Times Literary Supplement,* from which we take this information, has stated recently that among their members there is "a quite extraordinarily high standard of English speech and culture." Evidence of the growth of a preference for English as a second language is afforded also by the fact that Scandinavian men of science show a growing disposition to publish the results of their researches in our language. We have mentioned this on two or three occasions within the last few months when giving an account of recent papers, and another instance is afforded by the papers of Krabbe and Kemp noticed in another paragraph this week. With one exception the articles to which we refer were published in the series of Scandinavian medical periodicals published under the general title *Acta.* The *Acta* dealing with surgery, gynecology, medicine, laryngology, pediatrics, skin diseases and syphilis, and radiology, are edited in Stockholm. The place of publication of *Acta Pathologica,* in which Kemp's paper appeared, is Copenhagen. Further, it will have been observed that Professor Moellgaard of Copenhagen not only contributed to our columns a paper on the gold treatment he has devised for tuberculosis, but wrote his book on the subject in English. First rate scientific work is being done in the Scandinavian countries, and we have also much to learn from them in matters of administration; Denmark, for instance, has solved its Poor Law problem with a completeness England may well envy. From the other point of view there is this to be remembered, that English is spoken by many more people who read than any other language, and that, owing to its directness and conciseness, when well written, and to the ease with which it assimilates Latin and Greek roots, it lends itself well to the expression of scientific facts and speculations. We may therefore look forward to a not distant time when the work done by the medical profession in Denmark, Norway, Sweden, and, we may add, Holland, will be better known than it is to-day, very much to the advantage of medical science throughout the world.

Danish Tuberculosis Treatment to Be Tested by Government.—A thorough test of the new treatment for tuberculosis, devised by Professor Mollgaard of the Royal Veterinary College of Copenhagen, will be made under the auspices of the U. S. Public Health Service before it will be available for distribution in the United States. The new preparation is called "sanocrysin." The material used consists of a preparation of gold in combination with thiosulphuric acid known as aurithiosulphate. Probably the sodium salt of this compound is what is used. On introduction into an individual this substance produces a rather severe reaction evidenced by nephritis, fever, skin rashes, and shock. This is interpreted by the Danish scientist as evidence of the solution of tubercle bacilli in the sick individual, as the same reaction with the same dose does not occur in normal individuals. To offset the severity of this reaction and in a measure to control it, Professor Mollgaard makes use of an antituberculosis serum, which is prepared by the Danish State Serum Institute, by injecting dead tubercle bacilli in either calves or horses.

After proving to his satisfaction that the cure was valuable in animals, Professor Mollgaard arranged with Dr. Secher of the Municipal Hospital in Copenhagen to test the cure out on human cases of tuberculosis. The report of this clinical investigation of its value was recently made in Copenhagen and the reports were favorable as to its value in certain types of pulmonary tuberculosis but doubtful as to its value in surgical tuberculosis and severe cases of pulmonary tuberculosis. Arrangements were then made for the testing of the material in England, but no reports of these experiments have been made.

An American pharmaceutical company has become interested in the distribution of this material in America, but inasmuch as part of the cure is a serum it is necessary, as provided by law in the interest of safeguarding the public health, that this new cure have the approval of the United States Public Health Service before it can be sold in the United States. The Public Health Service, through its Hygienic Laboratory, has arranged with the best equipped scientific men in this field to carry out a series of animal experiments and has arranged for the study of the cure in clinical cases in America under the direction of a Danish physician who has used it in Denmark. These studies are being pushed with the greatest rapidity.

Ligation of the Splenic Artery in a Case of Essential Thrombocytopenia (Werlhoff's Disease).—Lemaire and Debaisieux (*Bulletin de l'Académe royale de médecine de Belgique*, March 29, 1924) endorse Franck's classification of the hemorrhagic diatheses, apart from hemophilia and scurvy, into essential thrombocytopenia (reduction of blood platelets) and to symptomatic thrombocytopenia of grave septic disorders, typhus fever, certain hepato-splenic syndromes, etc. These disorders are also separated from the angiopathic purpuras, including anaphylactic purpura, in which the platelet content of the blood is subject to marked variations in both directions. Essential thrombocytopenia sets in in apparent good health with cutaneous purpura, and especially, copious bleeding from the mucous membranes; rupture of arteries may result in voluminous hematomas. The platelets drop below 20,000 and may even apparently disappear. Giant platelets frequently appear. The coagulation time remains normal but the bleeding time is prolonged; retraction of the clot is slow and imperfect. Splenectomy, first recommended by Kaznelson has given excellent results in these cases. In the case in a boy of fifteen years reported by the authors, however, the general condition was so poor that splenectomy seemed too dangerous. The platelets were reduced to 2,000, there was copious intestinal hemorrhage and epistaxis, with extreme anemia, faintness on the least movement and a pulse rate of 140. Ligation of the splenic artery at the hilum was thought of but deemed too lengthy an operation, and ligation of the splenic at the upper border of the pancreas was substituted. A median incision was made under ether, the gastrohepatic omentum broken through, the stomach drawn downward and to the left, a buttonhole made through the peritoneum over the artery at about the third pancreatic branch, and the vessel ligated, the whole operation occupying but fifteen minutes. In nineteen days, the platelets rose steadily to 238,000, the red cells from 1,030,000 to 3,400,000, and the general condition showed radical improvement. The hemorrhages stopped three days after the operation. There were no evidences of pancreatic insufficiency in the stools or urine. No Jolly bodies were found, showing that functioning of the spleen was not annulled. Ligation of the splenic artery is believed to be indicated in these cases when the general condition is so poor as to preclude splenectomy.

Spinal and Cranial Injuries in Breech Deliveries.—R. N. Pierson (*Surgery, Gynecology, and Obstetrics,* December, 1923), presents the following conclusions:

1. Birth injury and shock in breech deliveries cause greater fetal mortality and morbidity than asphyxia.

2. Unnecessary haste in breech extractions, prompted by fear of fetal asphyxia, often causes obstetrical complications leading to birth injuries.

3. The diagnosis of death from asphyxia in breech deliveries is only justified when, a, there is strong clinical evidence of asphyxia, but none of injury; and, b, when complete autopsy shows characteristic signs of asphyxia, but none of injury.

4. The incidence of breech extraction may be diminished by, a, the practice of external version when possible; b, and by stricter limitation of the indications for version and breech extraction.

5. The high mortality and morbidity of breech deliveries may also be reduced by:

a. A management of labor and delivery that will effect full dilatation of the soft parts.

b. Accommodating, in delivery, the long axis of the child to the axes of the pelvis, thus avoiding dangerous angulations. And by accommodating the longest diameters of the body, shoulders, and head to the longest diameters of the pelvis, thus avoiding a dangerous degree of traction and suprapubic pressure.

Is the Virulence of Streptococci Increased in Putrid Tissue?—Heinz Küstner (*Zentralblatt für Gynäkologie,* February 2, 1924) found that putrid tissue favored the development of a general infection. This fact constitutes a theoretical reason for the emptying of the uterus in protracted abortion. The expectant treatment is successful only when the wall of granulation tissue is formed rapidly at a time when the virulence of the streptococci is increasing. If abundant other bacteria which suggest the presence of a putrid process are found in the uterine discharge in addition to virulent germs, the emptying of the uterus is absolutely indicated.

ILETIN INSULIN, LILLY

Pure · Stable
Constant in Unitage

Iletin (Insulin, Lilly) is supplied in containers of two sizes: 5 c.c. vials and 10 c.c. vials. Both the 5 c.c. and 10 c.c. vials bear the same designation: U·10, U·20 and U·40.

To distinguish between the two sizes it will be necessary, for example, to order as U·10 5 c.c. vials or U·10-10 c.c. vials.

In absence of specifications as to size wanted, the 5 c.c. vials will be supplied.

PITUITARY EXTRACT LILLY

Pure · Stable · Uniform in Strength

Purity—This extract contains the active principle of the posterior lobe of the pituitary gland in a state of purity not attained heretofore on a commercial scale.

Stability—It will remain active over a long period. Test lots have been boiled with but little loss of activity.

Uniformity—Special methods have been devised for bringing each lot to the same standard of strength.

Pituitary Extract, Lilly, is supplied in two strengths, obstetrical and surgical; order as follows:

No. 117—Obstetrical 1-2 c.c. Ampoules
No. 118—Obstetrical 1 c.c. Ampoules
No. 119—Surgical 1 c.c. Ampoules

These ampoules are packed six in a box, each in an individual carton.

Write for additional information.
All Lilly Products are supplied by the Drug Trade.

THIOCOL SYRUP "ROCHE"

A valuable remedy, fully described in New and Nonofficial Remedies.

Thiocol Syrup does not disguise the condition by simply alleviating the symptoms but exerts a direct curative effect upon the area of infection.

Does not contain any narcotic or palliative drugs, does not constipate, does not upset digestion. May be safely administered to the youngest children.

Dosage: One-half to four teaspoonfuls, according to age, three times a day.

Original bottles contain 6 fluid ounces

Four Books of Permanent Value

PYE—Surgical Handicraft *New Ninth Edition*

Edited by W. H. Clayton-Greene, C.B.E., M.B., F.R.C.S., Surgeon to St. Mary's Hospital, London, and Lecturer on Surgery in the Medical School. Ninth revised edition (1925). Octavo. Over 600 pages, 343 Illustrations and 14 plates. $7.00 net.

Here is a new revised edition of a work which for forty years has held a unique place in surgical literature. To generation after generation of house surgeons it has been a friend in need. Every senior student and every intern should hasten to possess a copy. But indeed, experienced surgeons and general practitioners will find valuable hints on nearly every page. The book deals with dressings, bandaging, the after care of operative cases, and all the surgical manipulations which usually fall to the house surgeon, or in private practice to the surgical assistant, or to the general practitioner who does minor surgery. The various chapters treat of the arrest of hemorrhage; retentive apparatus; fractures, dislocations, and sprains; wounds, ulcers, and burns; cases requiring prolonged mechanical treatment; minor surgery and kindred subjects; special cases connected with the head and throat; certain surgical and general emergencies; administration of anesthetics; preparing patients for operation, urinalysis, use of X-rays in diagnosis and treatment, and surgical case-taking. Eight leading specialists have contributed special chapters: Anesthesia, by Joseph Blomfield, M.D.; Blood Transfusion, by T. Joekes, M.B., M.R.C.S.; The Ear, Nose, Throat, Larynx, and Head Injuries, by H. W. Carson, F.R.C.S.; The Eye, by Leslie Paton, F.R.C.S.; The Treatment of the Teeth, by Norman Bennett, L.D.S., M.R.C.S.; Poisoning and Urine Testing, by Sir Wm. Henry Wilcox, K.C.I.E., M.D.; X-Rays and the Taking of Skiagrams, by George Harrison Orton, M.D.; Recent Advances in Diagnosis and Treatment of Syphilis, by A. Fleming, F.R.C.S.

WALKER—Introduction to Dermatology *New Eighth Edition*

By Sir Norman Walker, LL.D., M.D., F.R.C.P. Eighth revised edition (1925). Octavo. 393 pages, 81 colored plates, 11 black and white plates, 80 text engravings. $7.00 net.

Sir Norman Walker's famous and deservedly popular work on the diseases of the skin has now reached its eighth edition. The volume has been largely rewritten and a number of new plates added. All the more common diseases are fully and lucidly described and wonderfully illustrated in natural colors so that diagnosis is made easy. The rarer conditions are given but little space. It is a very practical and almost ideal work for the student and general practitioner, while specialists in dermatology will gladly add to their reference libraries this new edition of the work of so high an authority as Sir Norman Walker of Edinburgh. As a matter of fact, the plates alone would be well worth the price of the book.

McKENDRICK and WHITTAKER—An X-Ray Atlas of the Normal and Abnormal Structures of the Body

By Archibald McKendrick, F.R.C.S. (Edin.), D.P.H., F.R.S.E., Surgeon in Charge of the Surgical X-Ray Department, Royal Infirmary, Edinburgh; Examiner, Royal College of Surgeons, Edinburgh; and Charles R. Whittaker, F.R.C.S. (Edin.), F.R.S.E., Assistant Lecturer on Anatomy, Surgeon's Hall, Edinburgh; Examiner, Royal College of Surgeons, Edinburgh. Large quarto, 240 pages, with 388 radiograms and 25 line drawings. Price, $10.00 net. *Just published.*

The success and high appreciation of Bertwistle's-Atlas of Radiographs of the Bones and Joints produced a strong demand for a good radiographic atlas including other parts of the body, and here it is. The authors have provided a series of excellent clear radiograms illustrating the normal and abnormal structures of the body, also the more common injuries and diseases. A few delineations of rare conditions have been added to lend interest to the work. While it is true that radiographic interpretation can only be satisfactorily learned from a careful study of actual negatives, and by assisting at "screen" examinations, to those who have not these facilities a good atlas is essential. The average practitioner frequently has difficulty in perceiving in the radiogram furnished to him just what the conditions really are and to be able to make comparison is a great help. The contents include: Normal Joints of the Limbs-Injuries and Diseases of the Limbs-Head, Neck, Thorax, and Spine-Abdomen-Appendix.

ROGERS and MUIR—Leprosy *Just Published*

By Sir Leonard Rogers, C.I.E., M.D., F.R.C.P., F.R.C.S., F.R.S., I.M.S. (Rtd.), Physician and Lecturer, London School of Tropical Medicine, and Ernest Muir, M.D., F.R.C.S., Research Worker in Leprosy, School of Tropical Medicine and Hygiene, Calcutta. Octavo. 312 pages, with 32 plates, numerous Charts and Diagrams and a Map showing the World Distribution of Leprosy. $4.75 net.

A clear clinical account of leprosy and its treatment, based on a large personal experience with especial attention to the early and more amenable stages. Including in amplified form the first three Croonian Lectures for 1924, delivered before the Royal College of Physicians of London by Sir Leonard Rogers. Altogether a most valuable and interesting exposition of the problem which has baffled medical science for over three thousand years. As *The Lancet* says: "It is likely to remain the standard work on this subject for many years to come."

Calcium and Phosphorus

The profound physiologic importance of calcium and phosphorus, especially in the so-called wasting diseases, is becoming increasingly evident, and the best form of calcium and phosphorus for administration is unquestionably calcium glycerophosphate.

ESKAY'S NEURO PHOSPHATES

contains calcium and phosphorus in the form of glycerophosphate, is rapidly absorbed and does not cause gastrointestinal irritation on long-continued use, as do the usual calcium salts.

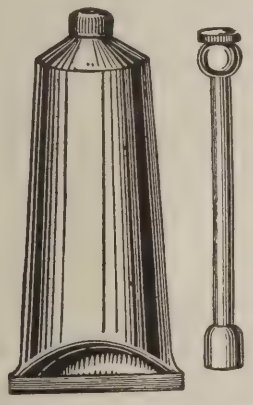
Intra-Vaginal Antisepsis

Dear Doctor:

That patient of yours who you have healed of Gonorrhea should not be re-infected. It is one of the uses of GLYEUTHYMENOL to prevent it.

The theory underlying the success of GLYEUTHYMENOL is simplicity itself. It is delivered at the cervix by a mechanical applicator and having a glycerine (not an oil) base it is distributed by osmosis into the uttermost histological fissures where an antiseptic must be if *prophylaxis* be attained. That is the whole story. Now contrast it with the suppository and douche as vehicles. The cocoa butter suppository would appear to be designed to defeat its purpose. The oil base will not unite with secretion (oil does not mix with water). Without union there can not be distribution. Without distribution how can there be antisepsis? The douche is a mere flush. We can think of no anatomical structure as difficult of sterilization by a flush as the vaginal walls. Can you?

Because of the method of distribution and the formula (sulphate of zinc, thymol, menthol, eucalyptol, etc.) physicians have found GLYEUTHYMENOL useful as an astringent to reduce congestion and inflammation and excess secretion, and for treatment of vaginitis, cervicitis, leucorrhea, etc. Our correspondents are enthusiastic over results in such cases—so much so as to be a constant surprise to us.



Full size standard tube contains 4 ounces.

Applicator 4½" long fits on top of tube. Simplifies treatment.

"What is the clinical experience?" you ask.

"Twelve thousand physicians are now dispensing it without *one single* material complaint," is our all sufficient answer.

Shouldn't GLYEUTHYMENOL be in your cabinet, Doctor? The enclosed coupon offers a very profitable "deal." Please do not delay. If you are in haste say so on the coupon, for GLYEUTHYMENOL has grown with such speed that we have never yet been able to ship a regular order when received.

Very truly yours,

NIXON STUART & BARKER

P. S. If you dispense through a druggist you must "O. K." the coupon for him, otherwise we cannot fill his order. This is a measure to keep ourselves ethical.

Our Special Introductory Offer

Send us your check for $4.00 and we will send you ¼ dozen Glyeuthymenol complete with applicator (normally retailing at $2.00 each) and with them free ¼ dozen Glyeuthymenol refills (normally retailing at $1.00 each).

Patients Who Have An Aversion to Plain Liquid Petrolatum

Such patients will find Cream of Nujol with Agar is smooth, creamy and of an exceptionally pleasant flavor. Infants and children take it readily because of its palatability.

Cream of Nujol with Agar is an effective lubricant in all types of intestinal stasis. During its passage along the intestinal tract it mixes with and softens the feces. Thus the fecal waste is kept soft, and is passed easily through the system and evacuated without straining.

This preparation contains no cathartic, saccharin or sugar ingredient. It may be prescribed with perfect safety for obese or diabetic patients.

Where no aversion to the taste of plain Liquid Petrolatum exists, Nujol will be found the ideal intestinal lubricant.

We shall be very pleased to send you a 9-oz. sample of Cream of Nujol with Agar upon request.

CREAM OF

Nujol

with

AGAR

Made by **NUJOL LABORATORIES, STANDARD OIL CO. (New Jersey)**
7 Hanover Square, New York

In cases of Dermatitis Calorica apply Antiphlogistine *cold*

IN cases of Dermatitis Ambustionis Erythematosa, where there is redness, accompanied with more or less heat of the affected part and slight swelling, apply Antiphlogistine as a *cold* dressing.

The hygroscopic properties of Antiphlogistine

are particularly valuable in cases of Dermatitis Ambustionis Bullosa. Aside from excluding the air, and relieving the smarting, the vesicular eruption and bullae are reduced, the serous exudate is deposited in the dressing, and the reparative process is greatly aided.

Antiphlogistine is an important "first aid" in all forms of inflammation, superficial or deep-seated. It absorbs the water from swollen tissues, relieves the pain, and acts in a physiological manner to re-establish normal circulation in the inflamed part.

When Antiphlogistine is used in time, suppuration following destruction of tissue, is often prevented.

Over 100,000 Physicians use Antiphlogistine regularly; it may be obtained at any Pharmacy.

Let us send you our free sample package and literature about Antiphlogistine, the world's most widely used ethical proprietary preparation.

MERCODEL

REG. U. S. PAT. OFF.

ITS SALIENT POINTS IN SYPHILIS

1. MERCODEL permits the physician to administer larger quantities of mercury in a shorter time, than by the use of the salts of mercury.
2. MERCODEL causes the lesions to disappear as rapidly as any other drug now being used.
3. MERCODEL being soluble in fats and lipoids, permeates every part of the body when given long enough.
4. MERCODEL can be given continuously until results are obtained. It does not exhaust or weaken the patient.
5. MERCODEL does not inhibit, but rather increases the immune processes of the body.
6. MERCODEL promotes an increase of the leucocytes.
7. MERCODEL never produces nitritoid or colloidoclastic reactions.
8. MERCODEL does not impair the liver or the kidneys.
9. MERCODEL may cause mild form of stomatitis or gingivitis which is easily controlled by proper dosage.
10. MERCODEL dosage of 5 cc. increasing upward enables the physician to determine in perfect safety the tolerance or idiosyncrasy of the patient to mercury.

N. B.—MERCODEL is administered painlessly through proper technique.

Here is the *ideal* treatment for Hay Fever

15-dose Series Mulford Pollen Extracts in Ever-Ready Hypo-Units

The thousands of physicians who use MULFORD HAY FEVER TREATMENT base their preference on the following points of excellence:

Advantages of Product

Prepared from pollens carefully selected, sifted and dried.

Stable in solution, thus avoiding inconvenience of mixing before use.

Accurately standardized, in terms of protein units.

Highest therapeutic and diagnostic value.

Advantages of Package

The MULFORD HYPO-UNIT package is the last word in convenience, safety and accuracy.

Each HYPO-UNIT contains one accurately measured dose, and is sterile and completely assembled, ready for instant use.

Used once, then thrown away, a feature appreciated by patient and physician alike.

Three intradermic tests supplied with each 15-dose treatment, to permit testing patient's increased tolerance during course of treatment.

Dosage

Desensitizing treatment, recommended for best results, should begin 4 to 8 weeks before attack is due, and 15 doses or more, of increasing strength, should be given. When the specific pollen appears in the air, doses should be greatly reduced.

How Supplied

TIMOTHY POLLEN EXTRACT, RAGWEED POLLEN EXTRACT, LAMB'S QUARTERS POLLEN EXTRACT and WORMWOOD POLLEN EXTRACT are furnished as follows:

15-Dose Treatment, including 3 Intradermal Tests and 15 Hypo-Units (doses 1 to 15)
5 cc Vial (D or E strength)
20 cc Vial (D strength)

What they will eat

Prescribe Puffed Grains to coax appetite back

WHEN convalescents refuse to take an interest in food, Quaker Puffed Grains often help coax back appetite.

Puffed Wheat and Puffed Rice are tempting dainties when offered with sugar and cream, or floated in a bowl of milk. They are so light, so airy, so delicately fragile, that it is hard to realize that they are such nutritious grains — rich wheat and rich rice — steam exploded to eight times normal size!

This breaking up of every tiny food cell assures easy digestion and assimilation. And, equally important, enjoyment of Puffed Grains encourages the liberal allowance of cream and milk so necessary in body-building.

Children enjoy Puffed Wheat and Puffed Rice, regarding them as confections which they are allowed to eat without restraint. When your little patients rebel at their daily allowance of what seems to them plainer, heartier food, advise mothers to make breakfast and luncheon seem more attractive by the introduction of Quaker Puffed Grains.

The one pre-eminently efficient organically combined iron and manganese product for the past 32 years, has been

GUDE'S PEPTO-MANGAN

(LIQUID--TABLET FORM)

DURING all of this time the physician who has not prescribed it has been the exception rather than the rule. This potent blood tonic and general reconstructive is now available in both liquid and *tablet form.*

It encourages corpuscular construction
It enhances hemoglobin formation
It aids general tissue oxygenation
It stimulates the failing appetite
It increases general reparative effort

It is thus of unquestioned and unquestionable value in

ANEMIC, CHLOROTIC and DEVITALIZED CONDITIONS

Our Bacteriological Wall Chart or our Differential Diagnosis Chart will be sent to any Physician upon request.

THE TREND IN CLINICAL MEDICINE
IS TOWARD THE MORE EXTENSIVE EMPLOYMENT OF

Tetanus Antitoxin

FOR CURATIVE PURPOSES

ANTITETANIC SERUM was at one time generally regarded as an efficient prophylactic rather than as a curative agent. But there is an unmistakable trend nowadays toward the use of antitetanic serum as a specific curative agent as well.

A prominent surgeon writes us: "A great deal of the pessimism in the use of serum for curative purposes is perhaps because it is not given by the best route and in large enough doses. My statistics, as far as I have gone at present, show that in cases that have received a dose of 30,000 units by vein the mortality is only 3 per cent. It will probably be much better than this if one should cut down to the cases that have received this dose in the first three days of the tetanus symptoms."

Certain it is that early diagnosis and large therapeutic doses have materially lowered the mortality.

TETANUS ANTITOXIN, P. D. & CO., commends itself to the discriminating physician because of its high refinement, small bulk, and gratifying reliability.

Our Tetanus Toxin is of such strength and uniformity that healthy young horses under treatment with it, consistently produce a native antitetanic serum of relatively high potency.

Then our methods of concentration have been developed to such a point that the globulin resulting from this native serum represents Tetanus Antitoxin of the highest quality, chemically and biologically.

Finally, our syringe package, fitted with an improved plunger, is proving decidedly satisfactory.

Requests for literature are always welcomed.

PARKE, DAVIS & COMPANY
DETROIT ~ MICHIGAN

TETANUS ANTITOXIN, P. D. & CO., IS INCLUDED IN THE N. N. R. BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION

NEURASTHENIA

is essentially a disturbance of the glands of internal secretion.

"Some authors speak well of preparations containing extracts of all these glands, and considerable improvement results from the exhibition of a preparation such as Hormotone in suitable cases."
(*A Manual of Neurasthenia*, Ivo Geikie Cobb, 1922.)

HORMOTONE

meets all the requirements of the treatment.

What "L & F" means on pharmaceuticals

L&F

EXPERIENCE

Our fifty years of experience stands back of every pharmaceutical bearing the "L & F" label. In our laboratories and manufacturing plant at Bloomfield, N. J. are the most modern, complete facilities for scientific tests and rigid scrutiny of every material and process.

If you are not receiving our quarterly publication, "Notes on New Remedies and Medical Progress," we shall be glad to send it to you regularly upon request.

In addition to being the distributors of Pebeco Tooth Paste and "Lysol" Disinfectant, we manufacture over 5,000 products. We call your attention especially to the following "L & F" preparations:

Zitysol

A saponified solution of a stable, organic chlorine compound. Non-irritant and practically odorless. Indicated wherever an antiseptic is required and for pruritus and parasitic skin diseases.

Ichthosan

A soothing anti-pruritic ointment for acute skin troubles.

"Lysol" Ointment

For skin disturbances particularly of parasitic origin.

Milk of Magnesia

Fluid Extract of Cascara

Aromatic and plain.

A new handle!

DESIGNED to meet the requirements of certain branches of surgery not heretofore covered by Bard-Parker knives. The new No. 5 handle combines the shape and balance of the ordinary scalpel with the advantages of a B-P detachable blade.

The handle is in one piece, with no springs, catches or other devices to get in the way, or to make sterilization uncertain. A dull finish prevents the handle from slipping when in contact with wet, rubber gloves.

The surgeon possessing the three Bard-Parker handles, *including the new No. 5 handle,* and the seven patterns of blades is enabled to perform a majority of operations formerly made with the wide varieties of solid knife.

Moreover, with a Bard-Parker knife, the surgeon has a new keen blade for every operation while saving half the cost of resharpening an ordinary scalpel.

One No. 5 (new style) handle and one half-dozen each of Nos. 10, 11 and 12 blades —$3.75.

Peacock's Bromides

An effective combination of five bromide salts that owes its exceptional therapeutic value to its purity, palatability and potency.

Indicated in **headache, epilepsy, sleeplessness, uterine congestion** and **all reflex, convulsive** and **congestive nervous disorders.**

Dose: One to three drams p. r. n.

PEACOCK CHEMICAL COMPANY **ST. LOUIS, MO.**

PARATHYRIN

A Solution for Intramuscular or Intravenous Injection Containing the Active Hormones of the Parathyroid Bodies

Parathyrin is used in the treatment of tetany, paralysis agitans, chorea and other conditions associated with a functionally deficient calcium metabolism such as tuberculosis, osteomalacia, varicose and indolent ulcers.

It has also been used experimentally in certain forms of deranged fat metabolism; in conjunction with insulin in coma of diabetic origin, as well as most convulsive states and in cases of diabetes showing acetonuria.

Ordinarily two doses each week are quite sufficient, but in extreme cases the doses of 1 cc may be given daily or on alternate days for several doses.

The same preparation in triple strength is likewise available for the unusual cases, but the single strength solution is supplied on all unspecified orders for Parathyrin.

Box of ½ dozen 1 cc. ampoules..... $2.00
Box of 100, 1 cc. ampoules..... 30.00

PARATHYRIN INCREASES BLOOD CALCIUM

A Typical Example of the Effect of Parathyrin When Administered to Normal Rabbits Kept on a Constant Standard Diet.

Each rabbit received three doses of single strength Parathyrin subcutaneously at three-day intervals, and were bled for the second test three days after receiving the last dose.

Rabbit No.	Blood Calcium Before Treatment	Blood Calcium After Treatment	Increase in Blood Calcium	Percentage Increase
1	19.5 mg.	22.4 mg.	2.9 mg.	14.9%
2	18.0 mg.	22.0 mg.	4.0 mg.	22.0%
3	15.5 mg.	19.1 mg.	3.6 mg.	23.0%
4	17.5 mg.	20.9 mg.	3.4 mg.	19.0%

Opiates Are Unnecessary

PHENALGIN

has made them so, and given to the practitioner a better, safer, and more effectual means of relieving and controlling pain.

In addition to its anodyne efficiency, **Phenalgin** has the following noteworthy advantages —

1 -- Does not create a habit.
2 -- Does not disturb the digestion.
3 -- Does not suppress the secretions.
4 -- Does not retard bowel action.
5 -- Is not subject to Government restrictions.
6 -- Requires no filling out of blanks or keeping of special records.

Is it surprising, therefore, that **Phenalgin** has so largely taken the place of the opiates in the treatment of **headache, neuralgia, rheumatism, painful menstruation, lumbago,** and so many other painful affections?

DIABAN DIABETIC FLOUR

Physicians welcome the facility with which it is now possible to maintain synchronously the patient's nourishment and control the sugar secretion through the employment of a low carbohydrate flour.

Diaban muffins are utilizable with or without insulin in mild or severe types of the malady, and their delicious flavor is a boon to the patient that hitherto he has been denied.

One Diaban muffin contains less than one third as much carbohydrates and only twice as much protein as found in an equal quantity of wheat bread. One package of Diaban Flour (2 days supply) makes 12 muffins, each muffin containing 5.0 grams carbohydrates, 5.3 grams protein, 3.3 grams fat, 71 calories.

Analysis and directions on every package. Diaban Flour is uniform and analysis always dependable. Physician's circular sent upon request.

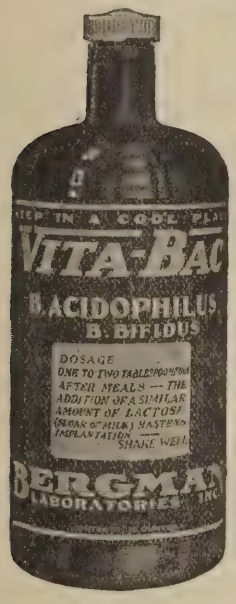
ELIMINATION of INTESTINAL PUTREFACTION BY TRANSFORMING THE FLORA



has been pointed out by eminent authorities as the first step in the treatment of intestinal toxemia.

That intestinal putrefaction and other toxic processes produced by the B. Coli, B. Welchii and allied organisms in the alimentary canal, is an all important factor in the causation of many bodily ills, has been definitely and positively established. The first consideration, therefore, in the treatment of auto-intoxication or intestinal toxemia, is not only to destroy the putrefactive organisms that are present, but to substitute an adequate amount of viable aciduric organisms, thereby approximating a condition in the intestine closely to that at birth, when the Bacillus Acidophilus and Bacillus Bifidus predominate. It has been shown that as long as the Bacillus Acidophilus predominates the intestinal tract, proper and normal functioning of the intestine takes place. Extensive clinical research and experimentation shows that no preparation of these desirable and important organisms [B. Acidophilus and B. Bifidus], can accomplish the foregoing as promptly or as satisfactorily as

VITA-BAC

A Pure Composite Milk Culture of

B. ACIDOPHILUS
and B. BIFIDUS

Administered in tablespoonful doses after meals, this pure composite milk culture of B. Acidophilus and B. Bifidus immediately changes the intestinal flora with destruction of the putrefactive bacteria; and an implantation of active and viable B. Acidophilus and B. Bifidus takes place in quantities that assure a relatively sterile condition throughout the intestinal tract.

Thus constipation, intestinal stasis, auto-intoxication and other intestinal conditions are quickly overcome without the necessity for the large bulky doses of lactic acid bacilli preparations hitherto available to the medical profession.

Distinct Advantages of Vita-Bac cultures of B. Acidophilus and B. Bifidus.

1. **Only small doses required to effect an implantation e. g. one to two tablespoonfuls after meals.**
2. **Does not have to be kept on ice to maintain purity and viability.**
3. **Easy to prescribe as all druggists stock Vita-Bac making it easily and quickly obtained by patients.**
4. **Marketed in a strictly ethical manner on your prescription only, with no literature or other reading matter on the trade package.**

We are preparing for free distribution to the medical profession, a series of interesting and informative booklets in scientific form on Intestinal Bacteriology; which will be mailed on request. The first booklet on "The Bacillus Acidophilus and Its Therapy" is now ready.

WELL DESERVED SUCCESS

LESS than three years ago S. M. A. was comparatively unknown to physicians throughout the country, yet by sheer merit alone it has steadily advanced to a prominent position among all fine products for the infant's diet.

We believe no other product has ever achieved such success in such a short time or made so many friends among physicians.

Once you have tried S. M. A. you will agree that its success has been well deserved, and we want you to have that experience. Just write us for trial package and literature.

THE LABORATORY PRODUCTS CO., Cleveland, Ohio

ALBUMINURIA

Bright's disease and allied conditions of renal impermeability readily respond to suitable organotherapy. We are not offering a *cure* for these conditions, but we have demonstrated that organotherapy, wisely directed, will do a great deal to ameliorate nephritis, and will, in many instances, entirely clear up albuminuria.

RENAL CO.

(*Harrower*)

containing renal glomerular tissue and pancreas (total), is producing results. Prescribe it in your next case of nephritis—1 sanitablet, q. i. d.
